The Arden Syntax for Medical Logic Systems, Version 3.0

Release 1 (Universal Realm)

Standard for Trial Use

October 2023

Publication of this standard for trial use (STU) has been approved by Health Level Seven International (HL7). This STU is not an accredited American National Standard. The feedback period on the use of this STU shall end 24 months from the date of publication. For information on submitting feedback see http://www.hl7.org/permalink/?SpecificationFeedback.

Following this 24-month feedback period, this STU, revised as necessary, may be resubmitted for further feedback or submitted to a normative ballot in preparation for approval by ANSI as an American National Standard. Implementations of this STU shall be viable throughout any subsequent normative ballot process and for up to six months after publication of the relevant normative standard.

IMPORTANT NOTES:

HL7 licenses its standards and select IP free of charge. **If you did not acquire a free license from HL7 for this document,** you are not authorized to access or make any use of it. To obtain a free license, please visit http://www.HL7.org/implement/standards/index.cfm.

If you are the individual that obtained the license for this HL7 Standard, specification or other freely licensed work (in each and every instance "Specified Material"), the following describes the permitted uses of the Material.

A. HL7 INDIVIDUAL, STUDENT AND HEALTH PROFESSIONAL MEMBERS, who register and agree to the terms of HL7's license, are authorized, without additional charge, to read, and to use Specified Material to develop and sell products and services that implement, but do not directly incorporate, the Specified Material in whole or in part without paying license fees to HL7.

INDIVIDUAL, STUDENT AND HEALTH PROFESSIONAL MEMBERS wishing to incorporate additional items of Special Material in whole or part, into products and services, or to enjoy additional authorizations granted to HL7 ORGANIZATIONAL MEMBERS as noted below, must become ORGANIZATIONAL MEMBERS of HL7.

B. HL7 ORGANIZATION MEMBERS, who register and agree to the terms of HL7's License, are authorized, without additional charge, on a perpetual (except as provided for in the full license terms governing the Material), non-exclusive and worldwide basis, the right to (a) download, copy (for internal purposes only) and share this Material with your employees and consultants for study purposes, and (b) utilize the Material for the purpose of developing, making, having made, using, marketing, importing, offering to sell or license, and selling or licensing, and to otherwise distribute, Compliant Products, in all cases subject to the conditions set forth in this Agreement and any relevant patent and other intellectual property rights of third parties (which may include members of HL7). No other license, sublicense, or other rights of any kind are granted under this Agreement.

C. NON-MEMBERS, who register and agree to the terms of HL7's IP policy for Specified Material, are authorized, without additional charge, to read and use the Specified Material for evaluating whether to implement, or in implementing, the Specified Material, and to use Specified Material to develop and sell products and services that implement, but do not directly incorporate, the Specified Material in whole or in part.

NON-MEMBERS wishing to incorporate additional items of Specified Material in whole or part, into products and services, or to enjoy the additional authorizations granted to HL7 ORGANIZATIONAL MEMBERS, as noted above, must become ORGANIZATIONAL MEMBERS of HL7.

Please see http://www.HL7.org/legal/ippolicy.cfm for the full license terms governing the Material.

Ownership. Licensee agrees and acknowledges that **HL7 owns** all right, title, and interest, in and to the Trademark. Licensee shall **take no action contrary to, or inconsistent with**, the foregoing.

Licensee agrees and acknowledges that HL7 may not own all right, title, and interest, in and to the Materials and that the Materials may contain and/or reference intellectual property owned by third parties ("Third Party IP"). Acceptance of these License Terms does not grant Licensee any rights with respect to Third Party IP. Licensee alone is responsible for identifying and obtaining any necessary licenses or authorizations to utilize Third Party IP in connection with the Materials or otherwise. Any actions, claims or suits brought by a third party resulting from a breach of any Third Party IP right by the Licensee remains the Licensee's liability.

Following is a non-exhaustive list of third-party terminologies that may require a separate license:

Terminology	Owner/Contact
Current Procedures Terminology (CPT) code set	American Medical Association https://www.ama-assn.org/practice-management/cpt-licensing
SNOMED CT®	SNOMED CT® International http://www.snomed.org/snomed-ct/get-snomed-ct or info@ihtsdo.org
Logical Observation Identifiers Names & Codes (LOINC®)	Regenstrief Institute
International Classification of Diseases (ICD) codes	World Health Organization (WHO)
NUCC Health Care Provider Taxonomy code set	American Medical Association. Please see www.nucc.org. AMA licensing contact: 312-464-5022 (AMA IP services)

The first version of this standard was developed under the auspices of the American Society for Testing and Materials (ASTM) and published in April 1992 as ASTM E1460-92. Subsequent versions, Version 2, 2.1, 2.5, 2.6, 2.7, 2.8 and Version 2.9 were developed and published by Health Level Seven International, Inc. (HL7). These versions were accepted as standards by the American National Standards Institute (ANSI) and The International Standards Organization (ISO). The previous standard, Version 2.10, was accepted as an ANSI standard in 2014. This version, 3.0, represents a revision of the previous ANSI version.

Arden Syntax for Medical Logic Systems

Contributor	**Andreas Csarmann, BSc** Medexter Healthcare GmbH

TABLE OF CONTENTS

What's New in Version 3.0

The principal change of version 3.0 is the addition of syntax to support HL7's Fast Healthcare Interoperability Resources (FHIR) standards. The document describes and illustrates the syntax needed to access data through services consistent with the FHIR 4.3.0 release. The added syntax (and the correlation of this new syntax with that in version 2.10) is intended to extend the functionality of the Arden standard without breaking backward compatibility.

Changes to version 2.10 now reflected in version 3.0:

- Section 12 in this document contains a description of the Arden approach to incorporation of the HL7 FHIR standard for access to the relevant data. The preference is to focus on FHIR resources that have become normative, but there are several data types that are consistently found in Arden MLMs that are reflected in normative resources; these are discussed and the Arden approach is illustrated.

1   SCOPE

This specification covers the sharing of computerized health knowledge bases among personnel, information systems, and institutions. The scope has been limited to those knowledge bases that can be represented as a set of discrete modules. Each module, referred to as a Medical Logic Module (MLM), contains sufficient knowledge to make a single decision. Contraindication alerts, management suggestions, data interpretations, treatment protocols, and diagnosis scores are examples of the health knowledge that can be represented using MLMs. Each MLM also contains management information to help maintain a knowledge base of MLMs and links to other sources of knowledge. Health personnel can create MLMs directly using this format, and the resulting MLMs can be used directly by an information system that conforms to this specification.

3 TERMINOLOGY

3.1 Definitions

3.1.1 Medical Logic Module (MLM), n

an independent unit in a health knowledge base. Each MLM contains maintenance information, links to other sources of knowledge, and enough logic to make a single health decision.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 time, n

a timestamp, it includes both a date and a time-of-day.

3.2.2 time-of-day, n

hours, minutes, seconds, and possibly, fractions of seconds past midnight.

3.2.3 date, n

Gregorian year, month, and day.

3.2.4 duration, n

a period of time (for example, **3 days**) that has no particular start or end point.

3.2.5 institution, n

a health facility of any size that will provide automated decision support or quality assurance.

3.2.6 event, n

a clinically meaningful change in state. This is often, but not always, reflected by a change in the clinical database. For example, ordering a medication is an event that could update the clinical database; when the stop time of the medication order is passed, the stopping of the medication would be an event, even though there might not be any change to the database.

3.3 Notation Used in This Standard

Throughout this standard, the location for optional elements is noted by placing the optional elements inside square brackets (**[ ]**). This is not to be confused with the element operator **[ ]** (see Section 9.12.18). Thus, **is [not] equal** means that **is equal** and **is not equal** are both valid constructs. The two most common optional elements are **not** and **of**.

4 SIGNIFICANCE AND USE

Decision support systems have been used for health care successfully for many years, and several institutions have assembled large knowledge bases. There are many conceptual similarities among these knowledge bases. Unfortunately, the syntax of each knowledge base is different. Since no one institution will ever define a complete health knowledge base, it will be necessary to share knowledge artifacts among institutions. A number of efforts have been instituted to increase the accessiblity of clinical knowledge resources, notably the Mobilizing Computable Biomedical Knowledge project.[8]

Many obstacles to sharing have been identified: disparate vocabularies, maintenance issues, regional differences, liability, royalties, syntactic differences, etc. This standard addresses one obstacle by defining a syntax for creating and sharing knowledge bases. In addition, the syntax facilitates addressing other obstacles by providing specific fields to enter maintenance information, assignment of clinical responsibility, links to the literature, and mappings between local vocabulary terms and terms in the knowledge base.

The range of health knowledge bases is large. This specification focuses on those knowledge bases that can be represented as a set of Medical Logic Modules (MLMs). Each MLM contains maintenance information, links to other sources of knowledge, and enough logic to make a single health decision. Knowledge bases that are composed of independent rules, formulae, or protocols are most amenable to being represented using MLMs.

This specification, which is an outcome of the Columbia-Presbyterian Medical Center 1989 Arden Homestead retreat on sharing health knowledge bases, was derived largely from HCOM, the decision modeling language of the HELP System originated at the LDS Hospital, Salt Lake City, UT (**1**)[9,] and CARE, the language of the Regenstrief Medical Record System of the Regenstrief Institute for Health Care, Indianapolis, IN (**2**).

Revision date: 10/04/2023   Print date: 10/4/2023

5   MLM FORMAT

5.1   File Format

An MLM is a stream of text stored in an ASCII file (ANSI X3.4-1986) [international users may extend this by using UNICODE encoding, but a conforming implementation need only implement X3.4]. One or more MLMs may be placed in the same file. Within a file, an MLM begins with the marker **maintenance:** and ends with the marker **end:**. MLMs may be separated by white space, as defined in Section 7.1.20 and/or comments as defined in Section 7.1.19.

Annex 2, in this document, includes a schema for the Arden Syntax that allows representation of XML-based MLMs that are fully consistent with the description of the Arden Syntax in this manual. An extensible stylesheet language transform (XSLT) is provided which will convert XML-based MLMs to the standard ASCII format.

5.2   Character Set

Within an MLM only the printable ASCII characters (ASCII 33 through and including 126), space (ASCII 32), carriage return (ASCII 13), line feed (ASCII 10), horizontal tab (ASCII 9), vertical tab (ASCII 11), and form feed (ASCII 12) may be used. The use of horizontal tab is discouraged because there is no agreement on how many spaces it represents. Other characters, such as the bell and backspace, are not allowed within the MLM. Inside the library category (Section 6.2), a string constant (Section 7.1.13) or comment (Section 7.1.19), these character set restrictions are lifted.

5.3   Line Break

Lines are delimited by line breaks, which are any one of the following: a single carriage return, a single line feed, or a carriage return-line feed pair.

5.4   White Space

The space, carriage return, line feed, horizontal tab, vertical tab, and form feed are collectively referred to as white space. See also Section 7.1.20.

5.5   General Layout

Annex A1 contains a context-free grammar (formal description) of Arden Syntax MLMs expressed in Backus-Naur Form **(3)**. See Appendix X2 for MLM examples. A typical MLM is arranged like this.

```
maintenance:
slotname: slot-body;;
slotname: slot-body;;
…
library:
slotname: slot-body;;
...
knowledge:
slotname: slot-body;;
...
resources:
slotname: slot-body;;
...
end:
```

5.6   Categories

An MLM is composed of slots grouped into three required categories, maintenance, library, and knowledge, and one optional category, resources. A category is indicated by a category name followed immediately by a colon (that is, **maintenance:**, **library:**, **knowledge:**, and **resources:**).White space may precede the category name and follow the colon, but no white space is allowed between the category name and the colon. Categories must appear in the order they appear in this standard.

5.7   Slots

Within each category is a set of slots.

Each slot consists of a slot name, followed immediately by a colon (for example, **title:**), then followed by the slot body, and terminated with two adjacent semicolons (**;;**) which is referred to as double semicolon. White space may precede the slot name and follow the colon, but no white space is allowed between the slot name and the colon. The content of the slot body depends upon the slot, but it must not contain a double semicolon, except inside comments (Section 7.1.19), string constants (Section 7.1.13), and mapping clauses (Section 7.1.18).

Each slot must be unique in the MLM, and categories and slots must follow the order in which they are listed in this standard. Some slots are required, and others are optional.

5.8   Slot Body Types

These are the basic types of slot bodies:

5.8.1   Textual Slots

A textual slot contains arbitrary text (except for double semicolon, which ends the slot). As the MLM standard is augmented, slots that are currently considered to be textual may become coded or structured. An example of a textual slot is the title slot, which can contain arbitrary text. For required textual slots, the text may be empty.

5.8.2   Textual List Slots

Some slots contain textual lists. These are lists of arbitrary textual phrases, optionally separated by single semicolons (**;**). An example of a textual list slot is the keywords slot. The list may be empty. It may not contain a double semicolon (which ends the slot).

5.8.3   Coded Slots

Coded slots contain a simple coded entry like a number, a date, or a term from a predefined list. For example, the priority slot can only contain a number, and the validation slot can contain only the terms **production**, **research**, etc.

5.8.4   Structured Slots

Structured slots contain syntactically defined slot bodies. They are more complex than coded slots and are further defined in Section 7. An example of this kind of slot is the logic slot.

5.9   MLM Termination

The end of the MLM is marked by the word **end** followed immediately by a colon (that is, **end:**). White space may precede the terminator and follow the colon, but no white space is allowed between the terminator and the colon.

5.10 Case Insensitivity

Category names, slot names, and the **end** terminator may be typed in uppercase (for example, **END**), lowercase (for example, **end**), or mixed case (for example, **eNd**). See also Sections 7.1.3 and 7.1.5.

6 SLOT DESCRIPTIONS

Next to each slot name is an indication of whether the slot is textual, textual list, coded, or structured, and whether it is required or optional. Slots must appear in the order they appear in this specification.

6.1   Maintenance Category

The maintenance category contains the slots that specify information unrelated to the health knowledge in the MLM. These slots are used for MLM knowledge base maintenance and change control. The maintenance category also contains information about the version of the Arden Syntax that is being used.

6.1.1   Title (textual, required)

The title serves as a comment that describes briefly what the MLM does. For example,

```
title: Hepatitis B Surface Antigen in Pregnant Women;;
```

6.1.2   Mlmname (coded, required)

The mlmname uniquely identifies an MLM within a single authoring institution. It is represented as a string of characters beginning with a letter and followed by letters, digits, period (.), minus (-), and underscores (_). An mlmname may be 1 to 80 characters in length. Mlmnames are insensitive to case. The mlmname is distinct from the name of the ASCII file, which happens to hold one or more MLMs. For example,

```
mlmname: hepatitis_B_in_pregnancy;;
        or
mlmname: hiv_screening.mlm;;
```

While mlmname is preferred as the name of this slot, filename is also permitted for backward compatibility.

6.1.3   Arden Syntax Version (coded, optional*)

The Arden Syntax version informs the compiler which version of the standard has been used to write the MLM. If this slot is missing, the MLM is assumed to be written with the ASTM E1460-1992 standard (which didn't include this slot). Otherwise, the slot is of the following form:

```
arden: Version <Version number of Arden Syntax standard>;;
```

The text is not case sensitive. For example,

```
arden: Version 2;;
arden: version 2.1;;
arden: version 2.5;;
arden: version 2.6;;
```

*   This slot is required for versions 2 and later of the syntax but is optional for backward compatibility. That is, if it is missing, the assumed version is version 1.

6.1.4   Version (textual, required)

The current version of the MLM is arbitrary text, up to 80 characters in length, as is convenient for the institution's version control system, such as SCCS (Software Change/Configuration Control System) or RCS (Revision Control System). It is suggested that versions start at 1.00 and advance by .01 for small revisions and by 1 for large revisions. The exact form of the version information is institution-specific but must allow determining which MLM is the most recent (see Section 11.2.4). For example,

```
version: 1.00;;
```

6.1.5   Institution (textual, required)

The institution slot contains the name of the authoring institution, up to 80 characters in length. For example,

```
institution: Columbia University;;
```

6.1.6   Author (textual list, required)

The author slot is free-form text. It should contain a list of the authors of the MLM, delimited by semicolons. The following format should be used: first name, middle name or initial, last name, comma, suffixes, comma, and degrees.

An electronic mail address enclosed in parentheses may optionally follow each author's name. Internet addresses are assumed. For example,

```
author: John M. Smith, Jr., M.D. (jms@camis.columbia.edu);;
```

6.1.7   Specialist (textual list, required)

The domain specialist is the person in the institution responsible for validating and installing the MLM. This slot should always be present but blank when transferring MLMs from one institution to another. It is the borrowing institution's responsibility to fill this slot and accept responsibility for the use of the MLM. The format is the same as for the author slot. For example,

```
specialist: Jane Doe, Ph.D.;;
```

 or

```
specialist: ;;
```

6.1.8   Date (coded, required)

The date of last revision of the MLM must be placed in this slot. Either a date or a date-time (that is, a point in absolute time composed of a date plus a time-of-day) can be used. The format for dates and for date-time combinations is ISO complete representation in extended format (with the **T** or **t** separator) with optional time zones (ISO 8601:1988 (E)). Dates are **yyyy-mm-dd** so that January 2, 1989 would be represented as 1989-01-02. The earliest date-time Arden Syntax must support is January 1, 1800 (1800-01-01T00:00:00Z). Times are **yyyy-mm-ddThh:mm:ss** with optional fractional seconds and optional time zones. Thus, 1:30 p.m. on January 2, 1989 UTC would be represented as 1989-01-02T13:30:00Z. For example,

```
date: 1989-01-02;;
```

6.1.9   Validation (coded, required)

The validation slot specifies the validation status of the MLM. Use one of the following terms:

a)   **production**—approved for use in the clinical system,

b)   **research**—approved for use in a research study,

c)   **testing**—for debugging (when an MLM is written, this should be the initial value), or

d)   **expired**—out of date, no longer in clinical use.

An example is:

```
validation: testing;;
```

MLMs should never be shared with a validation status of **production**, since the domain specialist for the borrowing institution must set that validation status.

6.2   Library Category

The library category contains the slots pertinent to knowledge base maintenance that are related to the MLM's knowledge. These slots provide health personnel with predefined explanatory information and links to the health literature. They also facilitate searching through a knowledge base of MLMs.

6.2.1   Purpose (textual, required)

The purpose slot describes briefly why the MLM is being used. For example,

```
purpose: Screen for newborns who are at risk for developing hepatitis B;;
```

6.2.2   Explanation (textual, required)

The slot explains briefly in plain English how the MLM works. The explanation can be shown to the health care provider when he or she asks why an MLM came to its decision. For example,

```
explanation: This woman has a positive hepatitis B surface antigen titer
    within the past year. Therefore her newborn is at risk for developing
    hepatitis B.;;
```

6.2.3   Keywords (textual list, required)

Keywords are descriptive words used for searching through modules. UMLS terms **(4)** are preferred but not mandatory. Terms are delimited by semicolons (commas are allowed within a keyword). For example,

```
keywords: hepatitis B; pregnancy;;
```

6.2.4   Citations (structured / textual, optional)

The citations slot allows for the documentation of citations to relevant literature to be documented within an MLM. There are two supported formats for the citations slot. The first is a textual format with no implied structure. The textual format is provided for backward compatibility and is a deprecated form. The second is a structured format described later in this section. When using the textual format, citations to the literature should be entered in Vancouver style **(5)**.

In the structured format, citations must be numbered, serving as specific references. The individual citations may also be assigned a type. The type should follow the number and specify the function of the citation for the particular MLM. Citation types are:

a)   **Support** – citations which support, verify, or validate the algorithm in the logic slot;

b)   **Refute** – citations which refute or offer alternatives to the algorithm in the logic slot;

For example,

```
citations:
  1. SUPPORT Steiner RW. Interpreting the fractional excretion of sodium.
     Am J Med 1984;77:699-702.
  2. Goldman L, Cook EF, Brand DA, Lee TH, Rouan GW, Weisberg MC, et al. A
     computer protocol to predict myocardial infarction in emergency
     department patients with chest pain. N Engl J Med 1988;318(13):797-803.
  ;;
```

Within the structured citations format, either Vancouver style **(5)** or OpenURL format (ANSI/NISO Z39.88) are acceptable forms for representing individual citations. It is anticipated that the OpenURL format will become the preferred form in future versions of this standard. Appendix X2 contains examples of citations formatted using the OpenURL format as part of the discussion of an XML schema for representing MLMs.

6.2.5   Links (structured / textual, optional)

The links slot allows an institution to define links to other sources of information, such as an electronic textbook, teaching cases, or educational modules. There are two supported formats for the links slot. The first is a textual format with no implied structure. The textual format is provided for backward compatibility and is a deprecated form. The second is a structured format described later in this section.

The structured format may either use the ad-hoc format first presented in Arden Syntax Version 2.0 or the OpenURL format (ANSI/NISO Z39.88) to represent individual links. The individual links are delimited by semicolons. The contents of the links are institution-specific.

Within the ad-hoc format, links to sites on intranets or the internet should be prefixed by the term URL (Uniform Resource Locator) and the title of the document and link text should follow the defined standards for representing protocols and data sources (e.g., "Document Title", 'FILE://link.html'; "Second Document", 'http://www.nlm.nih.gov/'). Electronic material can also be entered in the **citations** slot above. The preferred form for structured links is:

link type, space (ASCII 32), link description (Arden Syntax term), comma, link text (Arden Syntax string). The only required element is the link text.

For example:

```
links:
    OTHER_LINK "CTIM .34.56.78";
    MESH_LINK "agranulocytosis/ci and sulfamethoxazole/ae";
    URL_LINK 'NLM Web Page', "http://www.nlm.nih.gov/";
    URL_LINK 'Visible Human Project',
        "http://www.nlm.nih.gov/research/visible/visible_human.html";
    URL_LINK 'DOS HTML File', "file://doslinx.htm";
    URL_LINK 'UNIX HTML File', "file://UnixLinx.html/";
;;
```

Each institution should test for expired links when receiving shared MLMs.

Appendix X2 contains examples of links formatted using the OpenURL format as part of the discussion of an XML schema for representing MLMs.

Note: This definition of the structured link differs from the 2.5 and previous versions of the structured link. This change was made to bring the structured link into conformance with the definitions of resource statements as defined in Section 6.4. Future version of the Arden Syntax standard will provide mechanisms for calling external links, it was decided to break backward compatibility on this issue to make the related constructs of links and resources have parallel structure. As the structured link has not been widely implemented it was felt that this was the proper time to make this change.

6.3   Knowledge Category

The knowledge category contains the slots that specify what the MLM does. These slots define the terms used in the MLM (data slot), the context in which the MLM should be evoked (evoke slot), the condition to be tested (logic slot), and the action to take should the condition be true (action slot).

6.3.1   Type (coded, required)

The type slot specifies what slots are contained in the knowledge category. The only type that has been defined so far is **data_driven**, which implies that there are the following slots: data, priority, evoke, logic, action, and urgency. For backward compatibility with the 1992 standard, the type **data-driven** (with a dash "-" separating the words) is also permitted. That is,

```
type: data_driven;;
```

or

```
type: data-driven;;
```

6.3.2   Data (structured, required)

In the data slot, terms used locally in the MLM are mapped to entities within an institution. The actual phrasing of the mapping will depend upon the institution. The details of this slot are explained in Section 11. In Section 0, this data mapping syntax has been extended to support FHIR. As with previous versions, the goal is to map relevant queries attributes retrieved within FHIR objects to clinically recognizable terms which will be used in the MLM's logic (see sections 11.2.2 and 12.6).

6.3.3   Priority (coded, optional)

The priority is a number from 1 (low) to 99 (high) that specifies the relative order in which MLMs should be evoked should several of them satisfy their evoke criteria simultaneously. An institution may choose whether or not to use a priority. The institution is responsible for maintaining these numbers to avoid conflicts. A borrowing institution will need to adjust these numbers to suit its collection of MLMs. If the priority slot is omitted, a default value of 50 is used. For example,

```
priority: 90;;
priority: 40.5;;
```

6.3.4 Evoke (structured, required)

The evoke slot contains the conditions under which the MLM becomes active. The details of this slot are explained in Section 14.

6.3.5 Logic (structured, required)

This slot contains the actual logic of the MLM. It generally tests some condition and then concludes **true** or **false**. The details of this slot are explained in Section 10.

6.3.6 Action (structured, required)

This slot contains the action produced when the logic slot concludes **true**. The details of this slot are explained in Section 13.

6.3.7 Urgency (coded, optional)

The urgency of the action or message is represented as a number from 1 (low) to 99 (high), or by a variable representing a number from 1 to 99. It is recommended that only integers be used as values in the urgency slot. Whereas the priority determines the order of execution of MLMs as they are evoked, the urgency determines the importance of the action of the MLM only if the MLM concludes true (that is, only if the MLM decides to carry out its action). If the urgency slot is omitted, or the variable representing urgency is null or outside the range 1 to 99, a default urgency of 50 is used. For example,

```
urgency: 90;;
urgency: urg_var;;
```

6.4   Resources Category*

The resources category contains a set of language slots that specify the textual resources on which the localized operator may be applied to obtain message contents in different languages (Section 9.8.11). Each language slot defines a set of key/value pairs that represent text constants in one specific language. At least one language slot is required if the resources category is defined. Its structure is:

```
resources:
  default: <language code>;;
  language: <language code>
    <set of language specific resources>;;
  language : <language code>
    <set of language specific resources>;;
```

The language codes are defined either as 2-character ISO 639-1 language codes or as combination of a 2-character ISO 639-1 language code and a 2-character ISO 3166-1 geographical code concatenated by an underscore. That is,

```
en
```

or

```
en_US
```

or

```
en_GB
```

or

```
fr
```

The ISO 639-1 code is mandatory while the extended combination of language and region is optional. Implementing systems that support localization using this extended language code (that is, a locale) can further define resources for the individual use of one specific language in different regions in the world.

*   This category is required for versions 2.9 and later of the syntax but is optional in older versions of the Arden Syntax. For ensuring backward compatibility, in older versions of the Arden Syntax,

```
resources:
    default: en;;
    language: en;;
```

has to be used in the case the value is missing.

6.4.1   Default (coded, required)

When using the localized operator, the implementing system has to retrieve the current user language setting. The default slot specifies what language setting has to be applied on the MLM when this user language cannot be retrieved by the implementing system. The value of the default slot is a language code as defined in Section 6.4. That is,

```
default: de;;
```

or

```
default: en_US;;
```

6.4.2   Language (coded, required)

The resources category also consists of one or more language slots. Each language slot contains of a language code as defined in Section 6.4 followed by a set of key/value pairs. Each key is a term (see Section 7.1.17) and its associated value is a string constant (Section 7.1.13). Each key is separated from its value by a colon (:). Each string defines the result of the localized operator when applied to the corresponding term. That is,

```
language: en
  'msg': "Caution, the patient has the following allergy to penicillin
    documented: ";
  'creat': "The patient's calculated creatinine clearance is %f ml/min."
;;
language: de
  'msg': "Vorsicht, zu diesem Patienten wurde die folgende Penicillinallergie
    dokumentiert: ";
  'creat': "Die berechnete Kreatinin-Clearance des Patienten beträgt %f
    ml/min."
;;
```

Each language slot must contain a unique language code (ISO 639.1) or optionally, a language code concatenated with an underscore "_" followed by a region code (ISO 3166-1). If these region codes are used, every entry associated with the language must contain a region code. For example,

```
language: en_US [..] ;;
language: en_UK [..] ;;
```

is valid while

```
language: en [..] ;;
language: en_US [..] ;;
```

is not.

The resources category may contain multiple language slots with a variety of <language code>_<region code> definitions. If the implementing system is only able to determine the required language at runtime, but not the required region, the first language slot matching that language is chosen. In the following example, if only the language code 'de' was known, the German definition (de_DE) would be used:

```
language: de_DE [..] ;;
language: de_AT [..] ;;
```

7 STRUCTURED SLOT SYNTAX

7.1 Tokens

The structured slots consist of a stream of character strings known as lexical elements or tokens. These tokens can be classified as follows:

7.1.1 Reserved Words

Reserved words are predefined tokens made of letters and digits. They are used to construct statements, to represent operators, and to represent data constants. Some are not currently used but are reserved for future use. The predefined synonyms of operators as well as the operators themselves are considered synonyms.

The existing reserved words are listed in Annex A2.

7.1.2 The

The is a special reserved word which is ignored wherever it is found in a structured slot (that is, it is treated exactly the same as white space). Its purpose is to improve the readability of the structured slots by permitting statements to be more like English.

7.1.3 Case Insensitivity

With the exception of the **format with …** format specification, the syntax is insensitive to the case of reserved words. That is, reserved words may be typed in uppercase, lowercase, and mixed case. For example, **then** and **THEN** are the same word. See Sections 5.10 and 9.8.2 and Annex A5.

7.1.4 Identifiers

Identifiers are alphanumeric tokens. The first character of an identifier must be a letter, and the rest must be letters, digits, and underscores (_). Identifiers must be 1 to 80 characters in length. It is an error for an identifier to be longer than 80 characters. Reserved words are not considered identifiers; for example, **then** is a reserved word, not an identifier. Identifiers are used to represent variables, which hold data.

7.1.5 Case Insensitivity

The syntax is insensitive to the case of identifiers. See Sections 5.10 and 7.1.3.

7.1.6 Special Symbols

The special symbols are predefined non-alphanumeric tokens. Special symbols are used for punctuation and to represent operators. They are listed in Annex A3.

7.1.7 Number Constants

Constant numbers contain one or more digits (**0** to **9**) and an optional decimal point (**.**). (As in Specification E 1238 and HL7 2.3, **.1** and **345.** are valid numbers.) A number constant may end with an exponent, represented by an **E** or **e**, followed by an optional sign and one or more digits. These are valid numbers:

```
0
345
0.1
34.5E34
0.1e-4
.3
3.
3e10
```

7.1.8 Negative Numbers

Negative numbers are created using the unary minus operator (**-**, see Section 9.9.4). The minus sign is not strictly a part of the number constant.

7.1.9 Time Constants

Time constants use the ISO extended format (with the **T** or **t** separator) for date-time combinations with optional fractional seconds (using **.** format) and with optional time zones (see Section 6.1.8).

7.1.10 Fractional Seconds

Fractional seconds are represented by appending a decimal point (**.**) and one or more digits (for example, **1989-01-01T13:30:00.123**).

7.1.11 Time Zones

The local time zone is the default. ISO Coordinated Universal Time (UTC) is represented by appending a **z** to the end (for example, **1989-01-01T13:30:00.123Z**). The local time zone can be explicitly stated by appending **+** or **-** hh:mm to indicate how many hours and minutes the local time is ahead or behind UTC. Thus EST (Eastern Standard Time, United States of America) time zone would use **1989-01-01T13:30:00-05:00**, which would be equivalent to **1989-01-01T18:30:00Z**.

7.1.12 Constructing Times

The + operator can be used to construct a time from durations. Here is an example of constructing a time: **1800-01-01 + (1993-1800)years + (5-1)months + (17-1)days** produces the value **1993-05-17**.

7.1.13 String Constants

String constants begin and end with the quotation mark (", which is ASCII 34). For example,

```
"this is a string".
```

There is no limit on the length of strings.

7.1.14 Internal Quotation Marks

A quotation mark within a string is represented by using two adjacent quotation marks. For example,

```
"this string has one quotation mark: "" ".
```

7.1.15 Single Line Break

Within a string, white space containing a single line break (see Section 5.3) is converted to a single space. For example,

```
"this is a string with
one space between 'with' and 'one'"
```

7.1.16 Multiple Line Breaks

Within a string, white space containing more than one line break is converted to a single line break.

```
"this is a string with

one line break between 'with' and 'one'"
```

7.1.17 Term Constants

Term constants begin and end with an apostrophe (' which is ASCII 39), and they contain a valid mlmname. For example,

---

```
'mlm_name'
```

7.1.18   Mapping Clauses

A mapping clause is a string of characters that begins with **{** and ends with **}** (ASCII 123 and 125, respectively). Mapping clauses are used in the data slot to signify institution-specific definitions such as database queries. The only requirement imposed on what is within the curly brackets is that curly brackets are not allowed within mapping clauses. The definition of comments and quotes inside mapping clauses is not specified by this standard; it is recommended that they be the same as those given in this standard. The Arden Syntax conventions for variable names, such as case insensitivity or the treatment of **the** as white space, need not be observed in a mapping clause. A **<mapping>** may (in an implementation-defined manner), within the curly brackets, use Arden variables; but it cannot set any Arden variables (Arden variables can only set by the **<var>**(s) on the left side of the assignment operator). Because of this, an MLM may require some modification before it can be processed at another institution, even if the other institution's compiler is set to skip over read mappings.

It is strongly recommended that MLM authors include comments to all the mapping clauses used in an MLM, so MLM recipients understand the intention of the mapping clause definition when sharing MLMs. Identifiers from the UMLS Metathesaurus could aid in identifying and describing the concepts in the comments. Authors should also put all literals and constants in the data slot, with explanation, to allow MLM recipients to more easily customize MLMs.

In Arden Syntax, version 3.0 and above, data relevant to an MLM can also be accessed using HL7 FHIR service methods (see Section 12). Syntax for FHIR-based queries is supported and will be extended with future versions, as HL7 FHIR is becoming a standard in data exchange. Note that for FHIR queries the curly brackets ({ and }) can be omitted, and the query therefore does not need institution-specific adjustments. To successfully write a FHIR query the syntax for the READ statements containing the mapping clause might be adapted, therefore refer to the appropriate chapters 11.2.1 and 11.2.2.

7.1.19   Comments

A comment is a string of characters that begins with **/*** and ends with ***/**. Comments are used to document how the slot works, but they are ignored logically (like **the** and other white space). Comments do not nest (e.g., **/* A comment /* */** is a single comment). A comment need not be preceded or followed by white space. Thus, **x/**/y** is the same as **x y**.

A comment may also be specified by the characters // through line break (see Section 5.3). When // is encountered, everything else on the line is ignored, including ***/**.

7.1.20   White Space

Any string of spaces, carriage returns, line feeds, horizontal tabs, vertical tabs, form feeds, and comments is known as white space. White space is used to separate other syntactic elements and to format the slot for easier reading. White space is required between any two tokens that may begin or end with letters, digits, or underscores (for example, **if done**). They are also required between two string constants. They are optional between other tokens (for example, **3+4** versus **3 + 4**). See also Sections 5.4 and 7.1.2.

7.1.21   Time-of-Day Constants

Time-of-day constants use the ISO format (for example, **18:30, 13:23:00.123**) without the date field. Constants are defined analogously to time constants as defined in 7.1.9. Time-of-day constants must contain at least the two-digit hour and minute components – in other words, they must consist of two integers ranging from 00 to 23, one colon, and two more integers ranging from 00 to 59. Seconds, fractional seconds and time zones are optional in time-of-day constants. Midnight is expressed as **00:00:00.000** and all other time-of-day values are greater than this value.

7.2 Organization

The tokens are organized into the following constructs:

7.2.1 Statements

A structured slot is composed of a set of statements. Each statement specifies a logical constraint or an action to be performed. In general, statements are carried out sequentially in the order that they appear. These are examples of statements (each is preceded by a comment that tells what it does):

```
/* this assigns 0 to variable "var1" */
let var1 be 0;
/* this causes the MLM named "hyperkalemia" to be executed */
hyperkalemia_present := call hyperkalemia;
/* this concludes "true" if the potassium is greater than 5 */
if potassium > 5.0 then
    conclude true;
endif;
```

7.2.2 Statement Termination

All statements except for the last statement in a slot must end with a semicolon (**;**). Thus, the semicolon acts as a statement separator. If the last statement of a slot has a terminating semicolon, there must be at least one white space between it and the double semicolon that terminates the slot (**;;;** is illegal but **;/**/;;** is legal). For example, the logic slot could contain:

```
logic:
    last_potas := last potas_list;
    if last_potas > 5.0 then
        conclude true;
    endif;
```

The syntax of the statements depends upon the individual slot. For a detailed description of the allowable statement types in each structured slot, see Sections 9.19, 11, 13, and 14.

7.2.3 Expressions

Statements are composed of reserved words, special symbols, and expressions. An expression represents a data value, which may belong to any one of the types defined in Section 8. Expressions may contain any of the following:

7.2.4 Constant

The data value may be represented explicitly using a constant like the number **3**, the time **1991-03-23T00:00:00**, etc. These are valid expressions:

```
null
true
345.4
"this is a string"
1991-05-01T23:12:23
```

7.2.5 Variable

An identifier (see Section 7.1.4) within an expression signifies a variable (see Section 7.2.7). These are valid variables:

```
var1
this_is_a_variable
a
```

7.2.6 Operator and Arguments

An expression may contain an operator and one or more sub-expressions known as arguments. For example, in **3+4**, **+** is an operator and **3** and **4** are arguments. The result of such an expression is a new data value, which is **7** in this example. Expressions may be nested so that an expression may be an argument in another expression. These are valid expressions:

```
4 * cosine 5
var1 = 7 and var2 = 15
(4+3) * 7
```

For details on operators, precedence, associativity, and parentheses, see Section 9.1.

7.2.7 Variables

A variable is a temporary holding area for a data value. Variables are not declared explicitly but are declared implicitly when they are first used. A variable is assigned a data value using an assignment statement (see Section 10.2.1). When it is later used in an expression, it represents the value that was assigned to it. For example, **var1** is a valid variable name. If the variable is used before it is assigned a value, then its value is **null**.

7.2.7.1 *Scope*

The scope of a variable is the entire MLM, not an individual slot. MLMs cannot read variables from other MLMs directly; thus, variables used in an MLM are not available to MLMs that are called (see Section 10.2.5). Non-Arden variables may be referenced and set within mapping statements, as restricted by the special rules for the individual mapping statements (for example, Section 11.2.4); in mapping statements, Arden variables may be referenced but not set. It is institution-defined how conflicts between Arden and non-Arden variable names are resolved.

7.2.7.2 *Special Variables*

Some variables, such as event variables, MLM variables, message variables, and destination variables, are special. They can only be used in particular constructs, and not in general expressions. These variables use special assignment statements in the data slot as defined in Section 11 (these special assignment statements are equivalent to declarations for the special variables). Special variables can be converted to strings and passed as arguments. The only valid operators on special variables are **is [not] equal** (Section 9.6.1), = (Section 9.5.1), and <> (Section 9.5.2).

8 DATA TYPES

The basic function of an MLM is to retrieve patient data, manipulate the data, come to some decision, and possibly perform an action. Data may come from various sources, such as a direct query to the patient database, a constant in the MLM, or the result of an operation on other data.

Data items may be kept in an ordered collection, called a list (ordered by position in the list, not by primary time). Lists are described further in Section 8.8.

The data are classified into several data types.

8.1 Null

Null is a special data type that signifies uncertainty. Such uncertainty may be the result of a lack of information in the patient database or an explicit **null** value in the database. Null results from an error in execution, such as a type mismatch or division by zero. Null may be specified explicitly within a slot using the word **null** (that is, the null constant). Entities of data type null may also have a primary time. The following expressions result in null (each is preceded by a comment):

```
/* explicit null */
   null
/* division by zero */
   3/0
/* addition of Boolean  */
   true + 3
```

8.2 Boolean

The Boolean data type includes the two truth values: true and false. The word **true** signifies Boolean true and the word **false** signifies Boolean false.

The logical operators use tri-state logic by using **null** to signify the third state, uncertainty. For example, **true or null** is true. Although **null** is uncertain, a disjunction that includes **true** is always true regardless of the other arguments. However, **false or null** is null because **false** in a disjunction adds no information. See Section 9.4 for full truth tables.

8.3 Number

There is a single number type, so there is no distinction between integer and floating-point numbers. Number constants (for example, **3.4E-12**) are defined in Section 7.1.7. Internally, all arithmetic is done in floating point. For example, **1/2** evaluates to **0.5**.

8.4 Time

The time data type refers to points in absolute time; it is also referred to as timestamp in other systems. Both date and time-of-day must be specified. Times back to the year 1800 must be supported and times before 1800-01-01 are not valid. Time constants (for example, **1990-07-12T00:00:00**) are defined in Section 7.1.9.

8.4.1 Granularity

The granularity of time beyond milliseconds is left to the implementing instance. Times stored in patient databases will have varying granularities. When a time is read by the MLM, it is always truncated to the beginning of the granule interval. For example, if the time-of-day is recorded only to the minute, then zero seconds are assumed; if only the date is known, then the time-of-day is assumed to be midnight.

8.4.2 Midnight

Midnight represents the beginning of a day and is expressed as T00:00:00 in a time data type, or as 00:00 as a time-of-day. 24:00 is **not** defined.

8.4.3   Now

The word **now** is a time constant that signifies the time when the MLM started execution. **Now** is constant through the execution of the MLM; that is, if **now** is used more than once, it will have the same value within the same MLM. **Now** inside a nested MLM will therefore be different from the **now** of the calling MLM.

8.4.4   Eventtime

One way that MLMs are evoked is by a triggering event. For example, the storage of a serum potassium in the patient database is an event that might evoke an MLM. The word **eventtime** is a time constant that signifies the time that the evoking event occurred (for example, the time that the database was updated). The **eventtime** is useful because MLMs may be evoked after a time delay; using **eventtime**, the MLM can query for what has occurred since the evoking event.

8.4.5   Triggertime

If the MLM is triggered directly by an event or another MLM, the **triggertime** is the same as the **eventtime**. If the MLM is triggered by a delayed trigger (see Section 14.3.3) or a delayed MLM call (see Section 13.2.5), the **triggertime** is the **eventtime** plus the delay time. Using **triggertime**, an MLM can trigger another MLM as if the second MLM were directly triggered by the event. The following inequality is guaranteed within a single MLM: **eventtime ≤ triggertime ≤ now**.

8.4.6   Currenttime

The word **currenttime** represents the system time at the instant the word is encountered during MLM execution. **Currenttime** differs from **now** in that **currenttime** constantly changes, while **now** remains constant while an MLM runs. Thus, the time required to execute an MLM (or query) can be determined by subtracting **now** from **currenttime**. The following inequality is guaranteed within a single MLM: **eventtime <= triggertime <= now <= currenttime**.

8.5   Duration

The duration data type signifies an interval of time that is not anchored to any particular point in absolute time. There are no duration constants. Instead one builds durations using the duration operators (see Section 9.10.7). For example, **1 day**, **45 seconds**, and **3.2 months** are durations.

8.5.1   Sub-Types

The duration data type has two sub-types: months and seconds. The reason for the division is that the number of seconds in a month or in a year depends on the starting date. Durations of months and years are expressed as months. Durations of seconds, minutes, hours, days, and weeks are expressed as seconds. There are no complex durations; the sub-type must be either months or seconds, but not both. For both types of durations, the duration amount may be a floating-point value.

The printing of a duration (that is, its string version) is independent of its internal representation. The health care provider who reads the result of an MLM may not realize that there are two sub-types of durations. How durations are printed is location specific. For example, the string version of **6E+08 seconds** might be **19.01 years**. See Section 9.8.

8.5.2   Time and Duration Arithmetic

Operations among times and durations are carried out as follows:

8.5.2.1   *Time - Time*

The subtraction of two times always results in a seconds duration. For example, **1990-03-01T00:00:00 - 1990-02-01T00:00:00** results in **2419200 seconds**.

8.5.2.2   *Time and Seconds*

The addition or subtraction of a time and a seconds duration results in a time. The arithmetic is straightforward: the time is expressed as the number of seconds since some anchor point (for example, **1800-01-01T00:00:00**) and the number of seconds is added to or subtracted from the time. For example, **1990-02-01T00:00:00 + 2419201 seconds** results in **1990-03-01T00:00:01**.

8.5.2.3   *Time and Months*

The addition or subtraction of a time and a months duration results in a time. The time is expressed in date and time-of-day format (for example, **1991-01-31T00:00:00**). Months are then added to or subtracted from the year and month components of the date (that is, **1991-01** in the example). If the resulting time is invalid due to the number of days in the new month, then the days are truncated to the last valid day of the month. For example, **1991-01-31T00:00:00 + 1 month** results in **1991-02-28T00:00:00**. If the month has a fractional component (for example, **1.1 months**) then integer months are used (that is, **1 month** and **2 months** in the example) and the result is computed through interpolation (the integer part of the months are added; then the fractional part is used on the next month for addition and on the previous month for subtraction). For example, **1991-01-31T00:00:00 + 1.1 months** results in **1991-02-28T00:00:00 + (0.1 * 2629746 seconds)** or **1991-03-03T01:02:54.6.** Explanation:

1991-01-31T00:00:00 + 1 month   = 1991-02-28T00:00:00

and

0.1 Months * 2629746 seconds / month [from 8.5.2.4]   = 262974.6 seconds

262974.6 seconds / (60 seconds / minute) / (1440 minutes /day)   = 3.0436875 days

0.0436875 days * 1440 minutes / day   = 62.91 minutes

                                   = 1 hour, 2 minutes, 54.6 seconds.

therefore

0.1 months   = 3 days 1 hour 2 minutes 54.6 seconds

thus

1991-01-31T00:00:00 + 1.1 months   = 1991-02-28T00:00:00 + 3 days 1 hour 2 minutes 54.6 seconds

                                   = 1991-03-03T01:02:54.6

Contrary to addition and subtraction on numbers, addition and subtraction of durations is not invertible. For example:

```
1993-01-31 + 1 month = 1993-02-28
1993-02-28 - 1 month = 1993-01-28 // (3 days earlier)
```

The order of operations is important: **(d+1 month)+1 day** may have a different value than **d+(1 month+1 day)**.

Other examples:

```
1991-01-31T00:00:00 - 2.1 months = 1990-11-26T22:57:05.4
1991-01-31T00:00:00 - 1.1 months = 1990-12-27T22:57:05.4
1991-04-30T00:00:00 - 0.1 months = 1991-04-26T22:57:05.4
```

8.5.2.4   *Months and Seconds*

Operations between months and seconds are done by first converting the months arguments to seconds using this conversion constant: 2629746 seconds/month (the average number of seconds in a month in the Gregorian calendar). For example, **1 month / 1 second** results in **2629746**.

8.6   String

Strings are streams of characters of variable length. String constants are defined in Section 7.1.13. For example,

---

```
"this is a string constant"
```

8.7 Term

Terms are currently used only to represent mlmnames within a structured slot and the link text portion of a structured link record. They are used only in a **call** statement (see Section 10.2.5). In the future they will be used for controlled vocabulary terms. Term constants are defined in Section 7.1.17. For example,

```
'mlm_name2'
'http://www.nlm.nih.gov/'
```

8.8 List

A list is an ordered set of elements, each of which may be null, Boolean, event, destination, message, term, number, time, duration, string, truth value, fuzzy number, fuzzy time, or fuzzy duration. There are no nested lists; that is, a list cannot be the element of another list. Lists may be heterogeneous; that is, the elements in a list may be of different types. There is one list constant, the empty list, which is signified by using a pair of empty parentheses: **()**. White space is allowed within an empty list's parentheses. Other lists are created by using list operators like the comma (**,**) to build lists from single items (see Section 9.2). For the output format of lists (including single element lists), see Section 9.8. For example, these are valid lists:

```
4, 3, 5
3, true, 5, null
, 1
()
```

If operators that expect list arguments are presented non-list arguments, the arguments are implicitly converted to single-element lists before the operator is applied.

8.9 Query Results

The result of a database query has a time value in addition to its data value.

Queries in the data slot retrieve data from the patient database or from other databases (for example, a controlled vocabulary database or a financial database). The result of a query is assigned to a variable for use in the other slots.

Queries returning data objects defined in accordance with the HL7 FHIR specification represent a special class of Arden query results, before assigned to a variable for use in other slots. These queries follow the rules defined for retrieving data objects using the FHIR read API but are constrained as defined below (Section 0).

8.9.1 Primary Time

Every item in the patient database is assumed to have some primary time (also called time of occurrence) associated with it. This time is defined as the medically relevant time for that query. For different entities, the primary time might signify different times. The primary time of a blood test might be the time it was drawn from the patient (or the closest to that time), whereas the primary time of a medication order might be the time the order was placed. If there is no medically relevant time for a data item, its primary time value should be equivalent to the **eventtime** (the time when the information was correct).

Implicit in every query to the patient database is a request for the primary time of the data. For example, when one retrieves a list of serum potassiums, one actually retrieves a list of pairs. Each pair contains a data value (the serum potassium numeric value) and a time value (for example, when the specimen was drawn).

In the case of data objects retrieved using a FHIR read API, the **eventtime** will be the *effectiveDateTime* for Observation resources and the *onsetDateTime* for Condition resources. (See Section 12.4 for the assignment of Primary Time for other FHIR resources.)

8.9.2 Retrieval Order

The result of a query is by default sorted in chronological order by the primary time of the result. The query may specify a different sort order.

8.9.3 Data Value

If a variable has been assigned the result of a query, then the use of the variable always refers to the data value. For example, if **potas** is a variable that has been assigned a list of serum potassiums, then one could use this statement to check the value of the most recent potassium measurement:

```
if latest potas > 5.0 then
    conclude true;
endif;
```

8.9.4 Time Function Operator

By using the **time** operator (see Section 9.17), one can set or retrieve the primary time associated with a variable or list element. The time retrieve function is described in Section 9.17.1. Setting primary times is discussed in the second paragraph of Section 9.17.1. For example, one could use this statement to check the primary time of the most recent potassium measurement:

```
if time of latest potas is within past 3 days then
    conclude true;
endif;
```

The **eventtime** is not necessarily the primary time of the evoking event. For example, if the storage of a serum potassium evokes an MLM, then the **eventtime** is the time that the result was stored in the database, but the primary time of the result is the time that it was drawn from the patient.

8.10 Object

An object results from use of the New statement (see Section 10.2.8), the **read as** statement (Section 11.2.2), the **destination as** statement (Section 11.2.9), or the **message as** statement (Section 11.2.7). It may contain multiple named attributes, each of which may contain any valid Arden type (including lists or objects). The latter capability allows for complex data structures to be manipulated by an MLM (lists within lists, for example) which would otherwise not be possible. Objects are also useful for interfacing MLMs with other object-oriented domain models (outside the scope of this document).

Objects defined using by referencing the attributes of an HL7 FHIR resource can be used directly (outside of the curly braces) in Arden logic.

8.11 Time-of-Day

The time-of-day data type refers to points in time that are not directly linked to a specific date. Time-of-day constants are analogously defined to time constants leaving the date portion blank. Time-of-day constants (for example, **23:20:00**) are defined in Section 7.1.13.

Operators that can use both time arguments and time-of-day arguments at the same time may follow the default time-of-day handling as defined in Section 9.1.5. The primary time handling is unaffected by this extension.

Note: To improve readability when describing this data type, the phrase "time-of-day" is usually hyphenated. These hyphens are NOT included when TIME OF DAY is used in an MLM.

8.12 Day-of-Week

The day-of-week data type is a special data type to represent specific days of the week to be used along with the "day of week" operator. Values of this data type are either expressed by constants or by integer values.

Day-of-week constants are defined by the following keywords:

MONDAY (1),
TUESDAY (2),
WEDNESDAY (3),
THURSDAY (4),
FRIDAY (5),
SATURDAY (6),
SUNDAY (7)

Note: To improve readability when describing this data type, the phrase "day-of-week" is usually hyphenated. These hyphens are NOT included when DAY OF WEEK is used in an MLM.

8.13 Truth Value

The data type of propositional variables is denoted by truth value or − for reasons of backwards compatibility −, equivalently, **Boolean**. A variable of this type stores real numbers between 0 and 1. The Boolean value **true** is equal to the truth value 1 and the Boolean value **false** is equal to the truth value 0. One may write:

```
Var := truth value 0; or, equivalently Var := false;
Var := truth value 0.667;
Var := truth value 1; or, equivalently Var := true;
```

8.14 Fuzzy Data Types

Fuzzy data types are fuzzy sets over one of the data types: number, time, or duration.

Fuzzy sets − as opposed to classical, crisp sets − provide a formal methodology to define and process sets or classes with unsharp boundaries.

A linguistic term in clinical descriptions/texts such as small or large, cold or warm, normal and elevated, enlarged and symmetric, diabetic and hypoxic is inherently a set, or class, with unsharp boundaries. A crisp boundary between neighboring concepts such as normal or pathological is − in the context of evaluating a particular patient − to a certain extent arbitrary and thus often not acceptable in real clinical situations.

For example, fever is defined as body temperature ≥ 38°C. What about 37.9°C or 37.8°C? Is it fever with a certain degree, e.g., 0.8 or 0.6? In clinical medicine, the answer should be yes. In computer-assisted clinical medicine, a diagnostic definition including fever ought to be enabled when measured 37.9°C at least to a certain degree, even if the crisp fever definition starts at 38°C.

Fuzzy sets make it possible to formally define linguistic terms with unsharp boundaries, to calculate degrees of truth if measurements fall into the borderline range, and fuzzy logic allows propagating the results through further calculation. The example MLMs X2.9, X2.10 and X2.11 illustrate the difference between crisp, simulated fuzzy, and fuzzy representation of the same calculation.

8.14.1 Fuzzy Number

The data type **fuzzy number** is dedicated to fuzzy sets over the reals. A fuzzy number partitions the reals into a finite number of (possibly unbounded) intervals, on each of which the fuzzy set is linear and continuous.

Formally, a fuzzy set $u : R \rightarrow [0, 1]$ can be stored into a variable of the type fuzzy number, if the following condition is met: There are $a_1 < a_2 < \ldots < a_k$ with $k >= 1$, such that **u** is linear on each open interval $(a_1; a_2)$, $\ldots, (a_{k-1}; a_k)$, **u** is constant on $(-\infty; a_1)$ and $(a_k; +\infty)$, and for each **x** in **R**, **u(x)** coincides either with the left limit or the right limit of **u** at **x**. If **u** is continuous, we then define:

```
Fuzzyset u := fuzzy set (a₁, t₁), (a₂, t₂), ..., (aₖ, tₖ);
```

where $t_i = u(a_i)$ for $i = 1, \ldots, k$ and **u(x)** is called the **characteristic function of the fuzzy set.**

The characteristic functions are allowed to contain discontinuities, which are not likely to be required inapplications, but should at least be definable. At discontinuity points we denote the left as well as the right limit. The first assignment is the value at that point, unless the second one appears twice. For instance,

```
TwotoThree := fuzzy set (2, truth value 0), (2, truth value 1), (2, truth
    value 1), (3, truth value 1), (3, truth value 0);
```

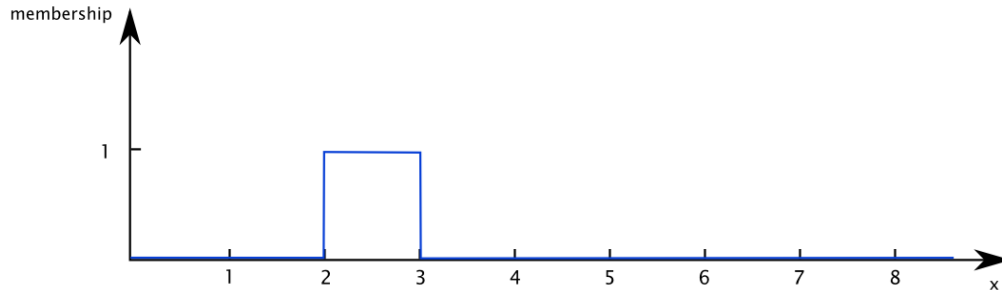

At point 2 there is a "discontinuity point" which means that approaching 2 from the left side the membership value is 0 while approaching 2 from the right side the membership value is 1. The question is which membership value is assigned to 2. The sentence "The first assignment is the value at that point, unless the second one appears twice." means in this example (fuzzy set `TwotoThree`) that the membership value at point 2 is 1, since the (2, 1) appears twice. If the fuzzy set is adjusted to

```
TwotoThree := fuzzy set (2, truth value 0), (2, truth value 1), (3, truth
    value 1), (3, truth value 0);
```

the membership value at point 2 is 0.

The example

```
OnetoFour := fuzzy set (1, truth value 0), (2, truth value 1), (2, truth
    value 1), (3, truth value 1), (4, truth value 0);
```

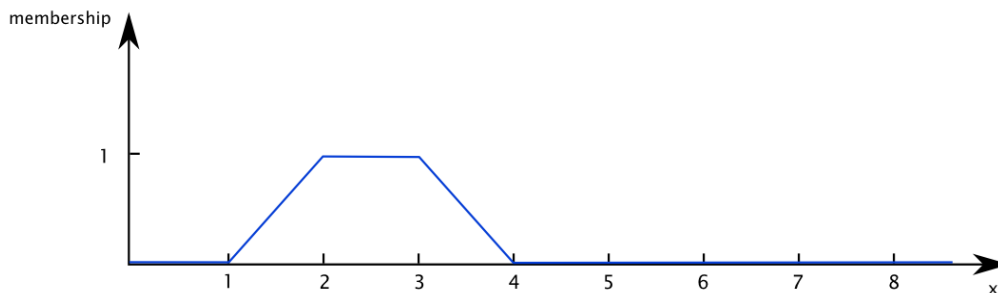

has no such "discontinuity point" at 2 and writing the (2, 1) twice is unnecessary but should have no effect to the interpretation of the function.

Fuzzy sets describing a symmetrical triangle around a single point, which is mapped to 1, are called triangular normal fuzzy sets. A simplified notation is permitted for these: an expression of the form fuzzy set (a - b, truth value 0), (a, truth value 1), (a + b, truth value 0), where a; b in R and b > 0, may also be written as:

```
a fuzzified by b
```

8.14.2 Fuzzy Time

The data type **fuzzy time** refers to fuzzy sets over times. Except for the simplified notation, all definitions of fuzzy numbers apply mutatis mutandis to fuzzy time.

For the simplified notation, a time constant can only be fuzzified by duration. Thus, we define

```
AfuzzyTime := today fuzzified by 1 day;
simple := 2009-10-10 fuzzified by 12 hours;
```

```
complex := fuzzy set (2009-10-10, truth value 0), (2009-10-11, truth value
    1), (2009-11-10, truth value 1), (2009-11-11, truth value 0);
```

8.14.3 Fuzzy Duration

All definitions of a fuzzy number apply mutatis mutandis to **fuzzy duration**.

```
simple := 14 days fuzzified by 1 day;
complex := fuzzy set (2 days, truth value 0), (3 days, truth value 1), (14
    days, truth value 1), (31 days, truth value 0);
```

8.15 Applicability

All simple data types (Truth Value, Boolean, Number, Time, Duration, String, Term, Query Results, Time-of-Day, Day-of-Week, Fuzzy Types) are endowed with an additional type of information called the **degree of applicability**. The degree of applicability stores a truth value that refers to the degree to which it is reasonable to use the value of a variable. It is 1 by default, and—whenever the program branches—reduced automatically according to the weight assigned to that particular branch. The programmer may decide to make explicit use of this concept but is not required to do so. To access the degree of applicability of an expression, the Arden Syntax programmer is referred to the **applicability [of]** operator (Section 9.19.4).

9 OPERATOR DESCRIPTIONS

9.1 General Properties

Operators are used in expressions to manipulate data. They accept one or more arguments (data values) and they produce a result (a new data value). The following properties apply to the operator definitions in this section.

9.1.1 Number of Arguments

Operators may have one, two, or three arguments. Some operators have two forms: one with one argument and one with two arguments. Operators are described as follows:

```
unary operator: one argument
binary operator: two arguments
ternary operator: three arguments
```

9.1.2 Data Type Constraints

Most operators work on only a subset of all the data types. Every operator description includes a type constraint that shows the position and allowable types of all of its arguments. Its general format is like this:

```
<num:type> := <num:type> op <num:type>
```

In this constraint, **op** is the operator being described.

Each **num** is one of the following:

1—the operator requires a single element

k, **m**, or **n**—the operator normally takes a single element but a list with 0, 1, or more elements may be used as described below. If the same letter appears more than once in a data type constraint, then the arguments so indicated must have the same number of elements; otherwise the operation results in **null**.

Each **type** is one of the following:

null—null data type

Boolean—Boolean data type

number—number data type

time—time data type

time-of-day—time-of-day data type

times—time and time-of-day data type

duration—duration data type

string—string data type

truth-value—truth value data type

item—not used in expressions, only in **call** statements (see Section 10.2.4)

any-type—null, Boolean, number, time, time-of-day, duration, string, truth-value, fuzzy-number, fuzzy-time, or fuzzy-duration

fuzzy-type—fuzzy-number, fuzzy-time, or fuzzy-duration

crisp-type—Boolean, number, time, time-of-day, duration, or string

non-null—Boolean, number, time, time-of-day, duration, string, truth-value, fuzzy-number, fuzzy-time, or fuzzy-duration

ordered—number, time, time-of-day, duration, string, or truth-value

<num:type>(s) to the right of the **:=** indicates the data type(s) of the argument(s). If the operator is applied to an argument with a type outside of its defined set, then **null** results. For example, ****** is not defined for the **time** data type so **3**1991-03-24T00:00:00** results in **null**. For most operators, **null** is not in the defined set, so **null** is returned when **null** is an argument. For example, **null** is not defined for + so **3+null** results in **null**.

<num:type> to the left of the **:=** indicates the data type of the result. Unless stated otherwise, the operators can also return **null** regardless of the stated usual result.

9.1.3   List Handling

Except as otherwise stated, lists are treated as follows. Each operator must apply the here described list handling first (if applicable) before the specific list handling as described in the respective operator description is applied.

When an operator has a template of the form **<n:type> := op <n:type>** or **<n:type> := <n:type> op**, the scalar operator is applied to each element of the list, producing a list with the same number of elements (if the list is empty, the resulting list is also empty). For example, **-(3,4,5)** results in **-3, -4, -5**.

Unary operators that act this way are:

```
not …
… is present
… is not present
… is null
… is not null
… is Boolean
… is not Boolean
… is number
… is not number
… is time
… is not time
… is time of day
… is not time of day
… is duration
… is not duration
… is string
… is not string
… is fuzzy
… is not fuzzy
… is crisp
… is not crisp
… is object
… is not object
… is <object-type>
… is not <object-type>
+ …
- …
… ago
… year
… years
```

```
… month
… months
… week
… weeks
… day
… days
… hour
… hours
… minute

abs [of] …
extract year [of] …
extract month [of] …
extract day [of] …
extract hour [of] …
extract minute [of] …
extract second [of] …
int …
round …
sqrt …
string …
length [of] …
uppercase …
lowercase …
trim …
localized …
defuzzified …
applicability [of] …
```

When an operator has a template of the form **<1:type> := op <n:type>** or **<1:type> := <n:type> op**, the operator is applied to the entire list, producing a single element. For example, **max(3,4,5)** results in **5**.

Unary operators that act this way are:

```
count [of] …
exist [of] …
```

```
avg [of] …
average [of] …
median [of] …
sum [of] …
stddev [of] …
variance [of] …
any [of] …
all [of] …
no [of] …
min [of] …
minimum [of] …
max [of] …
maximum [of] …
last [of] …
first [of] …
earliest [of] …
latest [of] …
string [of] …
… is list
… is not list
index min [of] …
index minimum [of] …
index max [of] …
index maximum [of] …
index earliest [of] …
index latest [of] …
```

When an operator has a template of the form **<m:type> := op <n:type>** or **<m:type> := <n:type> op**, the operator is applied to the entire list, producing another list. For example, **increase(11,15,13,12)** results in **(4, -2, -1)**.

Unary operators that act this way are:

```
slope [of] …
increase [of] …
decrease [of] …
percent increase [of] …
% increase [of] …
percent decrease [of] …
% decrease [of] …
interval [of] …
extract characters [of] …
sort [data|time] …
reverse …
```

When an operator has a template of the form **<n:type> := <n:type> op <n:type>**, the scalar operator is applied pair-wise to the elements of the lists, producing a list with the same number of elements (if the list is empty, the resulting list is also empty). For example, **(1,2)+(3,4)** results in **(4,6)** and **( ) + ( )** results in **( )** .

If one of the operands is a single element and the other operand has n elements, the single element is replicated n times. For example, **1+(3,4)** is equivalent to **(1,1)+(3,4)** and results in **(4,5)**.

If the numbers of elements in the two arguments differ and one argument is not a single element, the result is **null**.

Binary operators that act this way are:

```
… or …
… and …
```

```
… = …
… eq …
… is …
… <> …
… ne …
… is not equal …
… < …
… lt …
… is less than …
… is not greater than or equal …
… <= …
… le …
… is less than or equal …
… is not greater than …

… is not after …
… occur equal …
… occur within past …
… occur not within past …
… occur within same day as …
… occur not within same day as …
… occur before …
… occur not before …
… occur after …
… occur not after …
… + …
… - …
… * …
… / …
… ** …
… before …
… after …
… from …
localized … by …
replace year [of] … with …
replace month [of] … with …
replace day [of] … with …
replace hour [of] … with …
replace minute [of] … with …
replace second [of] … with …
```

The following operators are of the form **<n:type> := <m:type> op <m:type>**; they replicate the arguments if necessary but may return a list with a different number of elements:

```
… where …
```

When an operator has a template of the form **<n:type> := <n:type> op₁ <n:type> op₂ <n:type>**, the scalar operator is applied triple-wise to each element of the lists, producing a list with the same number of elements (if the list is empty, the resulting list is also empty). For example, **(1, 2) is within (0, 2) to (3, 4)** results in (**true, true**).

If one of the operands is a single element and the other operands have n elements, the single element is replicated n times. If two of the operands are a single element and the other operand has n elements, the single elements are replicated n times. For example, **(1, 2) is within 2 to (3, 4)** is equivalent to **(1, 2) is within (2, 2) to (3, 4)** and results in **(false, true)**.

If the number of elements in any pair of arguments differ and one argument is not a single element, the result is **null**.

Ternary operators that act this way are:

```
… is within … to …
… is not within … to …
… is within … preceding …
… is not within … preceding …
… is within … following …
… is not within … following …
… is within … surrounding …
… is not within … surrounding …
… occur within … to …
… occur not within … to …
… occur within … preceding …
… occur not within … preceding …
… occur within … following …
… occur not within … following …
… occur within … surrounding …
… occur not within … surrounding …
```

When an operator has a template of the form **<n:type> := op₁ <1:type> op₂ <m:type>**, the operator is applied to the entire second argument, producing a new list. The first argument must be a single element (if not, the result of the operator is **null**). For example, **min 2 from (5, 3, 4)** results in (**3, 4**).

Binary operators that act this way are:

```
min … from …
minimum … from …
max … from …
maximum … from …
last … from …
first … from …
latest … from …
earliest … from …
index min … from …
index minimum … from …
index max … from …
index maximum … from …
index earliest … from …
index of … from …
add … to …
at least … from …
at most … from …
```

When an operator has a template of the form **<n:type> := op₁ <n:type> op₂ <m:type>**, the operator is applied to the entire second argument, producing new list. The first argument is typically a single element. For example, **1 is in (0, 3)** results in **false** and **(1, 2, 3) is in (0, 3)** results in (**false, false, true**).

Binary operators that act this way are:

```
nearest … from …
… is in …
… is not in …
index nearest … from …
remove … from …
```

When an operator has a template of the form **<n:type> := <k:type> op <m:type>**, the operator is applied to the entire two lists, producing a new list. For example, **1, (3, 4)** results in (**1, 3, 4**).

Binary operators that act this way are:

```
… , …
… merge …
… || …
… seqto …
```

9.1.4   Primary Time Handling

Queries attach primary times to their results (see Section 8.9.1). Some operators maintain those primary times and others lose them. Except as otherwise stated, primary times are treated as follows.

9.1.4.1   *Unary Operators*

Unary operators maintain primary times. In this example, **result1** still has primary times attached if **data1** is the result of a query:

```
result1 := sin(data1);
```

9.1.4.2   *Binary and Ternary Operators*

Binary and ternary operators maintain primary times if all operands have primary times and all of the primary times are equal. If any operand is missing a primary time or if the primary times are not all equal, the primary time is lost.

Example (primary times are the same, the primary time is kept):

Data Values: 6 :=   2   *   3;

Time Values: (Jan 1)   (Jan 1)   (Jan 1);

Example (primary times are different, then primary time is lost):

Data Values: 42 :=   6   *   7;

Time Values: (null)   (Feb 1) (Jan 1);

9.1.5   Time-of-Day Handling

Operators that are defined for operands of "any" type, ordered types, etc. are not affected by time-of-day values. For example, aggregation operators such as the average operator still compute a result from a homogeneous list of time-of-day values, but return null if time-of-day values and time values are combined. Those operators that can be used with combined time-of-day and time values are defined in the next sections.

9.1.5.1   *Default Time-of-Day Handling*

Some binary and ternary operators can combine time and time-of-day values as operands as defined in the next section. In this case, as the time-of-day data type is a sub-type of the time data type, the operators automatically use the common information part of the operands, which is the time-of-day-fraction of the

given time value, and ignore the date information of the other operand (see examples of simple comparison operators in Section 9.5).

Operators that follow the default time-of-day handling are

- simple comparison operators (Section 9.5)

- is after/before (Section 9.6.12, 9.6.13)

9.1.5.2   *Role of Midnight*

Operators where the order of the arguments may indicate that the midnight boundary may be spanned are

is within ... to … (Section 9.6.6)

- is within ... to … preceding/following (Section 9.6.7, 9.6.8)

- is within … to … surrounding … (Section 9.6.9)

- Arithmetic operators (Section 9.9)

9.1.5.3   *Undefined Operators for Time-of-Day Values*

Operators for which time-of-day data types are not allowed as arguments are

- 'is within same day as': **undefined** for time-of-day operands as the required information for the comparison (date) is not present; returns null

- 'within past': **undefined** for time-of-day operands as the reference of the comparison is usually a fixed date and time; returns null

9.1.6   Applicability Handling

In general, every binary and ternary operator calculates the applicability of its result as the minimum of the applicability values of all parameters if not stated otherwise in the following definitions. Every unary operator sets the applicability of its result to 1 if not otherwise stated below. These rules also apply to the component-wise application of the operator on elements of lists.

9.1.7   Operator Precedence

Expressions are nested structures, which may contain more than one operator and several arguments. The order in which operators are executed is decided by using an operator property called precedence. Operators groups into several precedence groups. Operators of higher precedence are performed before operators of lower precedence. For example, the expression **3+4*5** (three plus four times five) is executed as follows: since ***** has higher precedence than **+**, it is performed first so that **4*5** results in **20**; then **+** is performed so that **3+20** results in **23**. Parentheses can always be used to override operator precedence.

9.1.7.1   *Precedence Table*

The operators are shown grouped by precedence in Annex A4.

9.1.8   Associativity

When an expression contains more than one operator within the same precedence group, the operators' associativity property decides the order of execution. The associativity of each operator is shown in Annex A4. There are three types of associativity:

9.1.8.1   *Left*

Left-associative operators are executed from left to right. For example, **3-4-5** has two subtractions (**-**). Since they are the same operator, they must be in the same precedence group. Since **-** is left-associative, **3-4** is performed first resulting in **(-1)**; then **(-1)-5** is performed, resulting in **(-6)**.

9.1.8.2 *Right*

Right-associative operators are executed from right to left. For example, **average sum 3** has two operators in the same precedence group. Since they are right-associative, **sum 3** is performed first resulting in **3**; then **average 3** is performed, resulting in **3**.

9.1.8.3 *Non-Associative*

Non-associative operators cannot have more than one operator from the same precedence group in the same expression unless parentheses are used. Thus the expression **2**3**4** is illegal since ****** (the exponentiation operator) is non-associative (however, **(2**3)**4** and **2**(3**4)** are both legal).

9.1.9 Parentheses

One can use parentheses to force a different order of execution. Expressions within parentheses are always performed before ones outside of parentheses. For example, the expression **(3+4)*5** is executed as follows: **3+4** is within parentheses, so it is performed first regardless of precedence, resulting in **7**; then ***** is performed so that **7*5** results in **35**. Similarly, **(2**3)**4** is a legal expression which results in **4096**.

9.2 List Operators

The list operators do not follow the default list handling. Primary times and applicabilities are maintained according to Section 9.1.4, unless otherwise specified.

9.2.1 **,** (binary, left-associative)

Binary**,** (list concatenation) appends two lists. Primary times and applicabilities of the individual list elements are maintained. Its usage is:

```
<n:any-type> := <k:any-type>, <m:any-type>
(4, 2) := 4, 2
(4, "a", null) := (4, "a"), null
```

9.2.2 **,** (unary, non-associative)

Unary**,** turns a single element into a list of length one. It does nothing if the argument is already a list. Its usage is (where **(3)** means a list with 3 as its only element):

```
<1:any-type> := , <1:any-type>
(3) := , 3
```

9.2.3 Merge (binary, left-associative)

The **merge** operator appends two lists, appends a single item to a list, or creates a list from two single items. It then sorts the result in chronological order based on the primary times of the elements (as defined in Section 9.2.4). All elements of both lists must have primary times; otherwise **null** is returned (the construct **x where time of it is present** can be used to select only elements of **x** that have primary times). The primary times and applicabilities are maintained. **Merge** is typically used to put together the results of two separate queries. The expression **x merge y** is equivalent to **sort time (x, y)**. Its usage is (assuming that **data1** has a data value of **2** and a time of **1991-01-02T00:00:00**, and that **data2** has data values **1, 3** and time values **1991-01-01T00:00:00**, **1991-01-03T00:00:00**):

```
<n:any-type> := <k:any-type> MERGE <m:any-type>
(1, 2, 3) := data1 MERGE data2
null := (4, 3) MERGE (2, 1)
```

9.2.4 Sort (unary, non-associative)

The **sort** operator reorders a list based on element contents, which are either the element values (keyword **data**) the primary times (keyword **time**), or the applicability (keyword **applicability**). An optional modifier may be used with the sort operator. If used, the modifier must be placed immediately after the **sort** keyword. The following keywords can be placed after the **sort** keyword: **data**, **time**, or **applicability**,

which are mutually exclusive. If no modifier is used, the sort operator defaults to a data sort. Direction of sorting is always ascending. For a descending sort, **reverse** can be used.

The sort options are considered to be part of the sort operator for precedence purposes. This resolves the potential conflict with the **time [of]** operator (9.17.1). Thus the expression "**sort time x**" should be parsed as "sort the list x by time" rather than as "extract the primary times from the list x and sort the list of times."

When sorting by primary times, if any of the elements do not have primary times, the result is **null.** (The sort argument can always be qualified by **where time of it is present**, if this is not desired behavior.) Elements with the same key will be kept in the same order as they appear in the argument. If any pair of element key cannot not be compared because of type clashes, **sort** returns **null** (that is, when sorting by data, any null value (or non-comparable value) results in **null**; when sorting by time, any null primary time results in **null**). The sorting by applicabilities is defined equivalent to sorting by primary times. Its usage is (assuming that **data1** has a data value of **30,10,20** with time values **1991-01-01T00:00:00**, **1991-02-01T00:00:00**, **1991-01-03T00:00:00** and applicability values **truth value 0.7, truth value 0.5, truth value 0.3**):

```
<n:any-type> := SORT <n:any-type>
<n:any-type> := SORT [DATA | TIME | APPLICABILITY] <n:any-type>
(10, 20, 30) := SORT DATA data1;
(30, 20, 10) := REVERSE (SORT DATA data1);
null := SORT DATA (3, 1, 2, null);
null := SORT DATA (3, "abc");
() := SORT TIME ();
(1, 2, 3, 3) := SORT (1, 3, 2, 3);
(30, 20, 10) := SORT TIME data1;
(20, 10, 30) := SORT APPLICABILITY data1;
(30, 10, 20) := REVERSE (SORT APPLICABILITY data1);
null := SORT APPLICABILITY (3, 1, 2, null);
() := SORT APPLICABILITY ();
```

The optional modifier **using ...** can be appended to the **sort** operator to control the calculation of the ordering. Thus, the following expressions can be used to sort the list by the data or the primary times of the elements:

```
<n:any-type> := sort <n:any-type> using it; // for sorting by data
<n:any-type> := sort <n:any-type> using time of it; // for sorting by time
```

The above mentioned expressions will be equivalent to the currently available expressions **sort time** and **sort data**. However, the **using** operator can be used to sort the list by an arbitrary calculation applied to each element of the list, e.g.:

```
<n:any-type> := sort <n:any-type> using sin it; // for sorting the list by
// the sin of each value
<n:any-type> := sort <n:any-type> using abs it; // for sorting the list by
// absolute values of the list elements
<n:any-type> := sort <n:any-type> using extract month it; // for sorting the
// list by month part of the list elements
```

If the **using** operator is applied to a list of objects, the list may be sorted by a specified field of the given objects, e.g.:

```
<n:object> := sort <n:object> using it.height; // for sorting the objects by
// their field "height"
<n:any-type> := sort <n:any-type> using time of it.value; // for sorting the
// objects by the primary time of their field "value"
```

The modifier using can contain any complex expression incorporating the **it** keyword.

9.2.5   Add … To … [At …] (ternary, non-associative)

The **add ... to ... [at ...]** operator expects an arbitrary data value as its first argument and a list as its second argument. It adds this element to the given list. If no position is given, the element will be added to the end

of the list. If a position is provided, the element is inserted at this position and the index of all elements from this to the end of the list will be increased by one. If the given position is greater than the cardinality of the list, the element will be appended at the end of the list. In case a negative position or 0 is given, the element will be appended at the beginning of the list. If the second argument is not a list, the argument is assumed a list with one element. When more than one position is given, the positions are first identified and then the elements are inserted. The usage of the **add ... to ... [at ...]** operator is:

```
<n+1:any-type> := ADD <1:any-type> TO <n:any-type>
<n+m:any-type> := ADD <1:any-type> TO <n:any-type> AT <m:number>
(1, 2, 3, 4) := ADD 4 TO (1, 2, 3);

(4, 1, 2, 3) := ADD 4 TO (1, 2, 3) AT 1;

(1, 2, 3, null) := ADD null TO (1, 2, 3);

(null, 4) := ADD 4 TO null;

(1, 2, 3, 4) := ADD 4 TO (1, 2, 3) AT 9;

(4, 4, 1, 2, 3) := ADD 4 TO (1, 2, 3) AT (1, -1);

(1, 2, 3, 4) := ADD 2 TO (1, 3, 4) AT INDEX OF 3 WITHIN (1, 3, 4);

(4, 1, 4, 2, 3) := ADD 4 TO (1, 2, 3) AT (1, 2);
```

9.2.6   Remove … From … (binary, non-associative)

The **remove ... from ...** operator expects a number or list of numbers as its first argument and a list as its second argument. The operator also accepts first and last as its first argument, they are interpreted as the number representing the last (the first) index in the given list. The operator removes the elements with the given indices from the list. The indices of all elements from the given index to the end of the list will be decreased by one. If the second argument is not a list, the argument is assumed a list with one element. When more than one position is given, the positions are first detected and then the elements are removed. The usage of the **remove ... from ...** operator is:

```
<n-m:any-type> := REMOVE <m:number> FROM <n:any-type>
(2, 1) := REMOVE 1 FROM (3, 2, 1);

("two", 4, 5) := REMOVE (1,3,6) FROM ("one", "two", 3, 4, 5, 6 days);

(3, 2, 1) := REMOVE null FROM (3, 2, 1);

(3, 2, 1) := REMOVE 8 FROM (3, 2, 1);

() := REMOVE (INDEX OF "3" WITHIN ("3", "3")) FROM ("3", "3");

(null) := REMOVE 2 FROM null;

() := REMOVE 1 FROM null;

(3, 2, 1) := REMOVE () FROM (3, 2, 1);
```

9.3   Where Operator

The **where** operator does not follow the default list handling or the default time handling.

9.3.1   Where (binary, non-associative)

The **where** operator performs the equivalent of a relational **select ... where ...** on its left argument. In general, the left argument is a list, often the result of a query to the database. The right argument is usually of type Boolean (although this is not required) and must be the same length as the left argument. The result is a list that contains only those elements of the left argument where the corresponding element in the right argument is Boolean **true**. If the right argument is anything else, including **false**, **null**, or any other type, then the element in the left argument is dropped. The **where** operator maintains the primary time(s) and applicabilities of the operand(s) to the left of **where**. The primary time(s) of the operand(s) to the right of **where** are dropped. Its usage is:

```
<n:any-type> := <m:any-type> WHERE <m:any-type>
(10, 30) := (10, 20, 30, 40) WHERE (true, false, true, 3);
```

Example:

```
7.38 :=        (7.34,        7.38,          7.4) WHERE time of it is within 20 minutes
following time of VentChange

(1/1 16:20)(1/1 18:01)  (1/1 16:20)   (Jan 1 02:06)
                    (Jan 1 16:12)
```

Where handles mixed single items and lists in a manner analogous to the other binary operators. If the right argument to **where** is a single item, then if it is **true**, the entire left argument is kept (whether or not it is a list); if it is not **true**, then the empty list is returned. If only the left argument is a single item, then the result is a list with as many of the single items as there are elements equal to **true** in the right argument. If the two arguments are lists of different length, then a single **null** results (the rules in Section 9.1.3 are used to replicate a single-element argument if necessary). For example,

```
1 := 1 WHERE true;
(1, 2, 3) := (1, 2, 3) WHERE true;
(1, 1) := 1 WHERE (true, false, true);
null := (1, 2, 3, 4) WHERE (true, false, true);
```

Where is generally used to select certain items from a list. The list is used as the left argument, and some comparison operator is applied to the list in the right argument. For example, **potassium_list where potassium_list > 5.0** would select from the list those values that are greater than 5.

Where can be used to filter out invalid data. For example, if a query returns either numeric values or text comments, the following can be used to select elements from the query that have proper numeric values:

```
queryResult where they are number
```

Similarly, if a query returns some values without primary times, the following can be used to select elements from the query that have proper primary times:

```
queryResult where time of it is present
```

In this example, the unary operator **time** is applied to the queryResult (which is what the value of "**it**" is), resulting in a list of times (for those results that have a primary time) and nulls (for those results that do not have a primary time). The unary operator **is present** is then applied to that list, give a list of Booleans: true where there is a primary time and false where there is no primary time. Finally, the **where** operator is used to remove those values that do not have primary times.

The following example follows the default time-of-day handling as it combines primary times (time values) with time-of-day constraints to select those blood glucose values that have been measured after lunch:

```
post_prandial_blood_glucoses := bc_values where they occurred within 13:00:00
    to 15:00:00;
```

The where operator can also be combined with day-of-week arguments, such as

```
labResults where day of week of time of them is in (SATURDAY, SUNDAY);
```

9.3.1.1   *It*

The word **it** and synonym **they** are used in conjunction with **where**. To simplify **where** expressions, **it** may be used in the right argument to represent the entire left argument. For example, **potassium_list where they > 5.0** would select those values from the list that are greater than 5. **It** is most useful when the left argument is a complex expression; for example, **(potassium_list + sodium_list/3) where it > 5.0** would assign the entire expression in parentheses to **it**. If there are nested **where** expressions, **it** refers to the left argument of the innermost **where**. If **it** is used outside of a **where** expression, then it has a value of **null**. An implementation of the Arden Syntax may choose to flag use of **it** outside a **where** expression as an error at compile time.

9.4   Logical Operators

9.4.1   Or (binary, left-associative)

The **or** operator performs the logical disjunction of its two arguments. If either argument is **true** (even if the other is not Boolean), the result is **true**. If both arguments are **false**, the result is **false**. If both arguments are truth values, the maximum of both arguments is returned. Otherwise the result is **null**. Its usage is as follows:

```
<n:truth-value> := <n:any-type> OR <n:any-type>
true := true OR false;
false := false OR false;
true := true OR null;
null := false OR null;
null := false OR 3.4;
truth value 0.4 := false OR (0.4 AS TRUTH VALUE) //see section 9.20.4 (as
    truth value)
true := true OR (TRUTH VALUE 0.7)//see section 8.13 (truth values)
truth value 0.5 := (0.5 AS TRUTH VALUE) OR (0.4 AS TRUTH VALUE)
(true, true) := (true, false) OR (false, true)
() := () OR ()
```

Its truth table is given here. **Other** means any of these data types: null, number, time, duration, or string.

	OR	TRUE	other truth value	Other	(Right argument)
(Left argument)	TRUE	TRUE	TRUE	TRUE	
	other truth value	TRUE	MAX(a, b)	NULL	
	Other	TRUE	NULL	NULL	

9.4.2   And (binary, left-associative)

The **and** operator performs the logical conjunction of its two arguments. If either argument is **false** (even if the other is not Boolean), the result is **false**. If both arguments are **true**, the result is **true**. If both arguments are truth values, the minimum of both arguments is returned. Otherwise the result is **null**. Its usage is:

```
<n:truth-value> := <n:any-type> AND <n:any-type>
false := true AND false;
null := true AND null;
false := false AND (0.4 AS TRUTH VALUE) //see section 9.20.4 (as truth
    value);
false := false AND (TRUTH VALUE 0.5)//see section 8.13 (truth values);
```

```
truth value 0.4 := (0.5 AS TRUTH VALUE) AND (0.4 AS TRUTH VALUE);
false := false AND null;
```

Its truth table is given here. **Other** means any of these data types: null, number, time, duration, or string.

	AND	TRUE	other truth value	other	(Right argument)
(Left argument)	TRUE	TRUE	FALSE	NULL	
	other truth value	FALSE	MIN(a, b)	FALSE	
	Other	NULL	FALSE	NULL	

9.4.3   Not (unary, non-associative)

The **not** operator performs the logical negation of its argument. If the argument is a truth value, the negation is the subtraction from 1. Its usage is:

```
<n:truth-value> := NOT <n:any-type>
true := NOT false
null := NOT null
truth value 0.8 := NOT (0.2 as TRUTH VALUE) //see section 9.20.4 (as truth
    value)
0.8 := NOT (TRUTH VALUE 0.2) //see section 8.13 (truth values)
(true, false) := NOT (false, true)
() := NOT ()
```

Its truth table is given here. **Other** means any of these data types: null, number, time, duration, or string.

NOT	TRUE	FALSE	Other truth value	other
	FALSE	TRUE	1- truth value	NULL

9.5   Simple Comparison Operators

9.5.1   = (binary, non-associative)

The = operator has two synonyms: **eq** and **is equal**. It checks for equality, returning **true** or **false**. If the arguments are of different types, **false** is returned. If an argument is **null**, then **null** is always returned. Primary times are not used in determining equality; the primary time of the result is determined by the rules in Section 9.1.4. Its usage is:

```
<n:Boolean> := <n:crisp-type> = <n:crisp-type>
false := 1 = 2;
(null, true, false) := (1, 2, "a") = (null, 2, 3);
null := (3/0) = (3/0);
false := 5 = ();
null := (1, 2, 3) = ();
null := null = ();
() := () = ();
null := 5 = null;
(null, null, null) := (1, 2, 3) = null;
```

```
null := null = null;
(true, true, false) := (1, 2, 3) = (1, 2, 4);
true := 1979-02-25T08:20:00 = 08:20:00;
```

Use **is present** or **exists** instead of = to test whether an argument is equal to **null**. See Sections 9.6.15 and 9.12.3.

9.5.2   <> (binary, non-associative)

The **<>** operator has two synonyms: **ne** and **is not equal**. It checks for inequality, returning **true** or **false**. If the arguments are of different types, **true** is returned. If an argument is **null**, then **null** is returned. Its usage is:

```
<n:Boolean> := <n:crisp-type> <> <n:crisp-type>
true := 1 <> 2;
(null, false, true) := (1, 2, "a") <> (null, 2, 3);
null := (3/0) <> (3/0);
false := 1979-02-25T08:20:00 <> 08:20:00;
```

9.5.3   < (binary, non-associative)

The **<** operator has three synonyms: **lt**, **is less than**, and **is not greater than or equal**. It is used on ordered types; if the types do not match, **null** is returned. Its usage is:

```
<n:Boolean> := <n:ordered> < <n:ordered>
true := 1 < 2;
true := 1990-03-02T00:00:00 < 1990-03-10T00:00:00;
true := 1990-03-02T00:00:00 < 13:00:00;
null := 13:00:00 < 14 hours;
true := 2 days < 1 year;
true := "aaa" < "aab";
null := "aaa" < 1;
```

9.5.4   <= (binary, non-associative)

The **<=** operator has three synonyms: **le**, **is less than or equal**, and **is not greater than**. It is used on ordered types; if the types do not match, **null** is returned. Its usage is:

```
<n:Boolean> := <n:ordered> <= <n:ordered>
<n:truth-value> := <n:crisp-type> <= <n:fuzzy-type>
true := 1 <= 2;
true := 1990-03-02T00:00:00 <= 1990-03-10T00:00:00;
true := 1990-03-02T00:00:00 <= 13:00:00;
true := 2 days <= 1 year;
true := "aaa" <= "aab";
null := "aaa" <= 1;
```

In addition, the **<=** operators support the same arguments as the **is [in]** operator. Supposing that the first argument is a crisp type and the second a corresponding fuzzy type, the **<=** operator then returns the **maximum** of u(x) for all x>=r, where r is the value stored in the first argument and u(x) is the fuzzy set provided by the second argument.

For example:

```
young := FUZZY SET (0, truth value 1),(15, truth value 1),(20, truth value
    0);
middle_aged := FUZZY SET (15, truth value 0),(20, truth value 1),(60, truth
    value 1), (70, truth value 0);

truth value 0 := 25 <= young;
truth value 1 := 25 <= middle_aged;
truth value 1 := 10 <= young;
truth value 1 := 10 <= middle_aged;
```

```
truth value 0.5 := 17.5 <= young;
truth value 1 := 17.5 <= middle_aged; // see picture
```

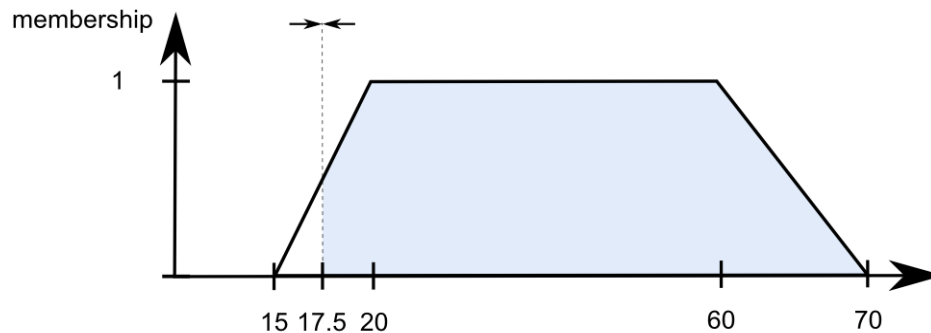

9.5.5   > (binary, non-associative)

The **>** operator has three synonyms: **gt**, **is greater than**, and **is not less than or equal**. It is used on ordered types; if the types do not match, **null** is returned. Its usage is:

```
<n:Boolean> := <n:ordered> > <n:ordered>
false := 1 > 2;
false := 1990-03-02T00:00:00 > 1990-03-10T00:00:00;
false := 1990-03-02T00:00:00 > 13:00:00;
false := 2 days > 1 year;
false := "aaa" > "aab";
null := "aaa" > 1;
```

9.5.6   >= (binary, non-associative)

The **>=** operator has three synonyms: **ge**, **is greater than or equal**, and **is not less than**. It is used on ordered types; if the types do not match, **null** is returned. Its usage is:

```
<n:Boolean> := <n:ordered> >= <n:ordered>
<n:truth-value> := <n:crisp-type> >= <n:fuzzy-type>
false := 1 >= 2;
false := 1990-03-02T00:00:00 >= 1990-03-10T00:00:00;
false := 1990-03-02T00:00:00 >= 13:00:00;
false := 2 days >= 1 year;
false := "aaa" >= "aab";
null := "aaa" >= 1;
```

The **>=** operators further support the same arguments as the **is [in]** operator. Supposing that the first argument is a crisp type and the second a fuzzy type, the **>=** operator then returns the **maximum** of u(x) for all r >= x, while r is the value stored in the first argument and u(x) is the fuzzy set provided by the second argument. For example:

```
young := FUZZY SET (0, truth value 1), (15, truth value 1), (20, truth value
    0);
middle_aged := FUZZY SET (15, truth value 0), (20, truth value 1), (60, truth
    value 1), (70, truth value   0);

truth value 1 := 25 >= young;
truth value 1 := 25 >= middle_aged;
truth value 1 := 10 >= young;
truth value 0 := 10 >= middle_aged;
truth value 0.5 := 17.5 >= middle_aged;
truth value 1 := 17.5 >= young; // see picture
```
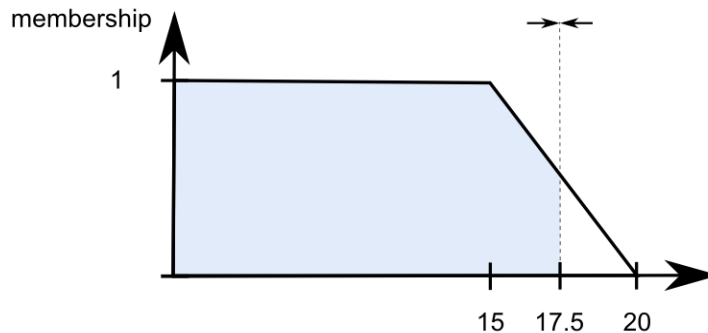

9.6 Is Comparison Operators

The following comparison operators include the word **is**, which can be replaced with **are**, **was**, or **were**. An optional **not** may follow the **is**, negating the result (using the definition of **not**, see Section 9.4.3). For example, these are valid:

```
surgery_time WAS BEFORE discharge_time
surgery_time IS NOT AFTER discharge_time
```

9.6.1 Is [not] Equal (binary, non-associative)

See Section 9.5.1.

9.6.2 Is [not] Less Than (binary, non-associative)

See Section 9.5.3.

9.6.3 Is [not] Greater Than (binary, non-associative)

See Section 9.5.5.

9.6.4 Is [not] Less Than or Equal (binary, non-associative)

See Section 9.5.4.

9.6.5 Is [not] Greater Than or Equal (binary, non-associative)

See Section 9.5.6.

9.6.6 Is [not] Within ... To (ternary, non-associative)

The **is within ... to** operator checks whether the first argument is within the range specified by the second and third arguments; the range is inclusive. It is used on ordered types; if the types do not match, **null** is returned. When used with time-of-day arguments, the order of the right and middle argument may be relevant, as the specified time frame may span over midnight.

When used with arguments that are not time-of-day arguments, operator functionally checks the following relationship

argument 2 <= argument 1 <= argument 3

and returns true if the relationship is satisfied and false if is not satisfied.

Its usage is:

```
<n:Boolean> := <n:ordered> IS WITHIN <n:ordered> TO <n:ordered>
true := 3 IS WITHIN 2 TO 5;
false := 3 IS WITHIN 5 TO 2;
true := 1990-03-10T00:00:00 IS WITHIN 1990-03-05T00:00:00 TO 1990-03-
    15T00:00:00;
true := 3 days IS WITHIN 2 days TO 5 months;
true := "ccc" IS WITHIN "a" TO "d";
false := 1990-03-10T15:00:00 IS WITHIN 16:00:00 TO 17:00:00;
```

If the middle and right argument of the last example are swapped, then the reference time frame spans midnight:

```
true := 1990-03-10T15:00:00 IS WITHIN 17:00:00 TO 16:00:00;
true := time of day of time of order IS WITHIN 22:00:00 to 02:00:00;
```

The last example returns true, if the order has been placed after 10 pm and 2 am, independently from the date of the order. The next example checks whether the measurement has been recorded on a weekday.

```
true := DAY OF WEEK OF TIME OF measurement IS WITHIN MONDAY TO FRIDAY;
```

Note that the day of week of a primary time results in a number, as well as the keywords MONDAY and FRIDAY. The following code snippet is not valid:

```
null := measurement OCCURRED WITHIN MONDAY to FRIDAY;
```

Caution must be used when using the day of week data type with the is . . . within operator, as well as the other comparison operators. Each day of the week is associated with an integer, with Monday = 1 through Sunday = 7 (see Section 8.12). Thus, the range of days specified can not begin before Monday and end after Sunday. For example.

```
true := WEDNESDAY IS WITHIN TUESDAY TO FRIDAY;
true := SATURDAY IS WITHIN FRIDAY TO SUNDAY;
false := SATURDAY IS WITHIN FRIDAY TO MONDAY;
(this returns false because 6 is not within 5 to 1)
```

9.6.7 Is [not] Within ... Preceding (ternary, non-associative)

The **is within ... preceding** operator checks whether the left argument is within the inclusive time period defined by the second two arguments (from the third argument minus the second to the third). Its usage is:

```
<n:Boolean> := <n:times> IS WITHIN <n:duration> PRECEDING <n:times>
true := 1990-03-08T00:00:00 IS WITHIN 3 days PRECEDING 1990-03-10T00:00:00;
```

9.6.8 Is [not] Within ... Following (ternary, non-associative)

The **is within ... following** operator checks whether the left argument is within the inclusive time period defined by the second two arguments (from the third argument to the third plus the second). Its usage is:

```
<n:Boolean> := <n:times> IS WITHIN <n:duration> FOLLOWING <n:times>
false := 1990-03-08T00:00:00 IS WITHIN 3 days FOLLOWING 1990-03-10T00:00:00;
```

9.6.9 Is [not] Within ... Surrounding (ternary, non-associative)

The **is within ... surrounding** operator checks whether the left argument is within the inclusive time period defined by the second two arguments (from the third argument minus the second to the third plus the second). Its usage is:

```
<n:Boolean> := <n:times> IS WITHIN <n:duration> SURROUNDING <n:times>
true := 1990-03-08T00:00:00 IS WITHIN 3 days SURROUNDING 1990-03-10T00:00:00;
```

This operator may be used with small durations as a short-hand notation for some comparisons that can be also represented by using the 'is within to' operator.

Examples:

```
false := time of day of time of request is within 2 hours surrounding 14:00;
(true, true, true, false, true) := time of day of time of measurements
                              are within 30 minutes surrounding 13:00;
```

9.6.10   Is [not] Within Past (binary, non-associative)

The **is within past** checks whether the left argument is within the time period defined by the right argument (**now** minus the right argument to **now**). Its usage is (assuming **now** is 1990-03-09T00:00:00):

```
<n:Boolean> := <n:times> IS WITHIN PAST <n:duration>
true := 1990-03-08T00:00:00 IS WITHIN PAST 3 days;
null := 12:00:00 IS WITHIN PAST 2 weeks;
```

9.6.11   Is [not] Within Same Day As (binary, non-associative)

The **is within same day as** operator checks whether the left argument is on the same day as the second argument**.** Its usage is:

```
<n:Boolean> := <n:time> IS WITHIN SAME DAY AS <n:time>
true := 1990-03-08T11:11:11 IS WITHIN SAME DAY AS 1990-03-08T01:01:01;
null := 12:00:00 IS WITHIN SAME DAY AS 1990-03-08T01:01:01;
```

9.6.12   Is [not] Before (binary, non-associative)

The **is before** operator checks whether the left argument is before the second argument; it is not inclusive. Its usage is:

```
<n:Boolean> := <n:times> IS BEFORE <n:times>
false := 1990-03-08T00:00:00 IS BEFORE 1990-03-07T00:00:00;
false := 1990-03-08T00:00:00 IS BEFORE 1990-03-08T00:00:00;
```

9.6.13   Is [not] After (binary, non-associative)

The **is after** operator checks whether the left argument is after the second argument; it is not inclusive. Its usage is:

```
<n:Boolean> := <n:times> IS AFTER <n:times>
true := 1990-03-08T00:00:00 IS AFTER 1990-03-07T00:00:00;
false := now is after 18:00:00;
```

The last example assumes, that the MLM runs before 18:00 (for example, now is 2005-01-01T17:30:00).

9.6.14   Is [not] In (binary, non-associative)

The **is in** operator does not follow the default list handling. It checks for membership of the left argument in the right argument, which is usually a list. If the left argument is a list, then a list results; if the left argument is a single item, then a single item results. If the right argument is a single item, then it is treated as a list of length one. If the first operand is **null**, **true** is always returned. If the second operand is **null** then **null** is returned, except the first one is also **null**. Primary times are retained only if they match (that is, the = operator is used for determining membership, except that **null** will match). Its usage is:

```
<n:Boolean> := <n:any-type> IS IN <m:any-type>
false := 2 IS IN (4, 5, 6);
(false, true) := (3, 4) IS IN (4, 5, 6);
true := null is in (1/0, 2);
false := day of week of (time of potassium) IS IN (SATURDAY, SUNDAY);
```

The operator **is in** also checks for containment in a fuzzy set, returning a **truth value**. The arguments are of a crisp and a fuzzy type. The fuzzy type must be derived from the rough crisp type of the other argument

(e.g.: if the crisp value is a number, the fuzzy value has to consist of a fuzzy number), otherwise **false** is returned. If we define a fuzzy and a crisp number as:

```
fuzzyVar := Fuzzy Set (0, truth value 0), (4, truth value 1), (5, truth value
    0);
crispVar := 2;
```

The crisp number may be correlated to the fuzzy set by the expression

```
crispVar IS IN FuzzyVar
```

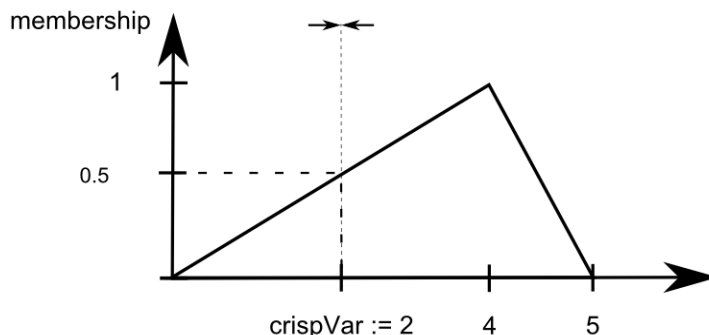

This simply gives the value of the fuzzy set (`fuzzyVar`) the point of the crisp value (`crispVar`). For the above example the result will be 0.5.

If one argument is **null**, then **null** is always returned.

Primary times are not used in determining the result. The primary time of the result is determined by the rules in Section 9.1.4. The usage of the **… [is] in…** operator is:

```
<n:truth-value> := <n:crisp-type> IS IN <n:fuzzy-type>
truth value 0.5 := 4 IS IN 5 fuzzified by 2;
truth value 0.5 := 2 IS IN Fuzzy Set (0, truth value 0), (4, truth value 1),
    (5, truth value 0);
```

The operator **is in** used by a FHIR **read as** statement can also check if a code is part of a valueset. In such cases the entire valueset might not be known inside the MLM, although it has a resolvable network URL and is in compliance with the FHIR standard. This specific use case applies only if a Coding object (part of root FHIR resources such as Observation.code.coding.code or Condition.code.coding.code) is on the left side of the comparison and the right side is a **Valueset** object (see Section 12.5.1):

```
<n:fhir-object-type> := READ AS <n:fhir.object-type> WHERE <return-
    value:coding> IS IN <n:Valueset>
/* Defining a valueset by its system URL and identifying code */
include_valueset := NEW Valueset WITH
    [system:="https://fhir.loinc.org/ValueSet", code:="LL770-1"];
/* By defining a FHIR read statement the IS IN operator can be applied to a
    coding and valueset. The FHIR repository will assert that only
    Observations included in the valuset are returned */
fhir_observation := READ AS Observation WHERE it.code.coding.code IS IN
    include_valueset;
```

See also Section 9.6.26.

9.6.15 Is [not] Present (unary, non-associative)

The **is present** operator has one synonym: **is not null**. (Similarly, **is not present** has one synonym: **is null**.) It returns **true** if the argument is not **null**, and it returns **false** if the argument is **null**. **Is present** never

returns **null**. This operator is used to test whether an argument is **null** since **arg=null** always results in **null** regardless of **arg**. Its usage is:

```
<n:Boolean> := <n:any-type> IS PRESENT
true := 3 IS PRESENT;
false := null IS PRESENT;
(true, false) := (3, null) IS PRESENT;
(false, true) := (3, null) IS NULL;
```

9.6.16   Is [not] Null (unary, non-associative)

See Section 9.6.15.

9.6.17   Is [not] Boolean (unary, non-associative)

The **is Boolean** operator returns **true** if the argument's data type is Boolean. Otherwise it returns **false**. **Is Boolean** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS BOOLEAN
true := false IS BOOLEAN;
true := 3 IS NOT BOOLEAN;
(false, true, false) := (null, false,3) IS BOOLEAN;
```

9.6.18   Is [not] Truth Value (unary, non-associative)

The **is Truth Value** operator returns **true** if the argument's data type is Truth Value. Otherwise it returns **false**. **Is Truth Value** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS TRUTH VALUE
true := TRUTH VALUE .44 IS TRUTH VALUE;
true := 3 IS NOT TRUTH VALUE;
(false, true, false) := (null, TRUTH VALUE .44, 3) IS TRUTH VALUE;
```

9.6.19   Is [not] Linguistic Variable (unary, non-associative)

The **is Linguistic Variable** operator returns **true** if the argument's data type is Linguistic Variable. Otherwise it returns **false**. **Is Linguistic Variable** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS LINGUISTIC VARIABLE
true := RangeOfAge IS LINGUISTIC VARIABLE;
true := 3 IS NOT LINGUISTIC VARIABLE;
(false, true, false) := (null, RangeOfAge,3) IS LINGUISTIC VARIABLE;
```

9.6.20   Is [not] Number (unary, non-associative)

The **is number** operator returns **true** if the argument's data type is number. Otherwise it returns **false**. **Is number** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS NUMBER
true := 3 IS NUMBER;
false := null IS NUMBER;
```

The **is number** is useful for ensuring that a list is all numbers before an aggregation operator is applied. This avoids returning **null**. For example,

```
sum(serum_K where it IS NUMBER);
```

9.6.21   Is [not] String (unary, non-associative)

The **is string** operator returns **true** if the argument's data type is string. Otherwise it returns **false**. **Is string** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS STRING
true := "asdf" IS STRING;
false := null IS STRING;
```

9.6.22 Is [not] Time (unary, non-associative)

The **is time** operator returns **true** if the argument's data type is time. Otherwise it returns **false**. **Is time** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS TIME
true := 1991-03-12T00:00:00 IS TIME;
false := null IS TIME;
```

9.6.23 Is [not] Time of Day (unary, non-associative)

The **is time of day** operator returns **true** if the argument's data type is time-of-day. Otherwise, it returns **false**. **Is time of day** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS TIME OF DAY
true := 23:20:00 IS TIME OF DAY;
true := 23:20:00.12 IS TIME OF DAY;
false := 1991-03-12T00:00:00 IS TIME OF DAY;
false := null IS TIME OF DAY;
```

9.6.24 Is [not] Duration (unary, non-associative)

The **is duration** operator returns **true** if the argument's data type is duration. Otherwise it returns **false**. **Is duration** never returns **null**. Its usage is:

```
<n:Boolean> := <n:any-type> IS DURATION
true := (3 days) IS DURATION;
false := null IS DURATION;
```

9.6.25 Is [not] List (unary, non-associative)

The **is list** operator returns **true** if the argument is a list. Otherwise it returns **false**. **Is list** never returns **null**. Its usage is:

```
<1:Boolean> := <n:any-type> IS LIST
true := (3, 2, 1) IS LIST;
false := 5 IS LIST;
false := null IS LIST;
```

The **is list** operator does not follow the default list handling because it does not operate on each item in the argument, but rather operates on the argument as a whole. Thus it never returns a list. Notice the difference:

```
true := (3, 2, "asdf") IS LIST;
(true, true, false) := (3, 2, "asdf") IS NUMBER;
```

9.6.26 [not] In (binary, non-associative)

The operator **in** is a synonym of **is in** and behaves in the same manner. Its usage is:

```
<n:Boolean> := <n:any-type> IN <m:any-type>
false := 2 IN (4, 5, 6);
(false, true) := (3, 4) IN (4, 5, 6);
true := null in (1/0, 2);
```

See also Section 9.6.14.

9.6.27 Is [not] Object (unary, non-associative)

The **is object** operator returns **true** if the argument is an object (any type of object defined with an Object declaration, as described in Section 11.2.17). Otherwise it returns **false**. Its usage is:

```
<n:Boolean> := <n:any-type> IS OBJECT
```

9.6.28 Is [not] <Object-Type> (unary, non-associative)

The **is <object-type>** operator returns **true** if the argument is an object of the named type (as previously defined with an Object declaration, as described in Section 11.2.17). Otherwise it returns **false**. Its usage is:

```
<n:Boolean> := <n:any-type> IS <OBJECT-TYPE>
RectType := OBJECT [x, y, width, height];
Rect := new RectType;
true := Rect IS RectType;
```

9.6.29 Is [not] Fuzzy (unary, non-associative)

The **is fuzzy** operator returns **true** if the argument's data type is a fuzzy number, fuzzy time or fuzzy duration. Otherwise it returns **false**. **Is fuzzy** never returns null. Its usage is:

```
<n:Boolean> := <n:any-type> IS FUZZY
false := 3 IS FUZZY;
true := (FUZZY SET (0, truth value 0), (1, truth value 1)) IS FUZZY;
true := (today fuzzified by 2 days) IS FUZZY;
```

9.6.30 Is [not] Crisp (unary, non-associative)

The **is crisp** operator returns **true** if the argument's data type is not a fuzzy number, fuzzy time or fuzzy duration. Otherwise it returns **false**. **Is crisp** never returns null. Its usage is:

```
<n:Boolean> := <n:any-type> IS CRISP
true := 3 IS CRISP;
false := (FUZZY SET (0, truth value 0), (1, truth value 1)) IS CRISP;
false := (today fuzzified by 2 days) IS CRISP;
```

9.7   Occur Comparison Operators

9.7.1   General Properties

The following comparison operators are analogous to the **is** comparison operators in Section 9.6. They use the word **occur** instead of **is**. The word **occur** can be replaced with **occurs** or **occurred**. An optional **not** may follow the **occur**, negating the result (using the definition of **not**, see Section 9.4.3).

The effect is that rather than using the left argument directly, the primary time of the left argument is used instead (that is, the **time** of the left argument is used; see Section 9.17). The following pairs are equivalent expressions:

```
time of var IS NOT BEFORE 1990-03-05T11:11:11
var OCCURRED NOT BEFORE 1990-03-05T11:11:11

time of surgery IS WITHIN THE PAST 3 days
surgery OCCURRED WITHIN THE PAST 3 days

time(a) IS WITHIN 1990-03-05T11:11:11 TO time(b)
a OCCURRED WITHIN 1990-03-05T11:11:11 TO time(b)
```

In the following operator examples, query_result is the result of a query; its primary time is 1990-03-05T11:11:11; and **now** is 1990-03-06T00:00:00.

Day-of-week data types are not allowed as arguments to occur comparison operators at this time. Time-of-day data types are allowed and follow standard time-of-day processing.

9.7.2   Occur [not] Equal (binary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR EQUAL <n:times>
false := query_result OCCURRED EQUAL 1990-03-01T00:00:00;
```

See also Section 9.7.11.

9.7.3   Occur [not] Within ... To (ternary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR WITHIN <n:times> TO <n:times>
true := query_result OCCURRED WITHIN 1990-03-01T00:00:00 TO 1990-03-
    11T00:00:00;
```

9.7.4   Occur [not] Within ... Preceding (ternary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR WITHIN <n:duration> PRECEDING <n:times>
false := query_result OCCURRED WITHIN 3 days PRECEDING 1990-03-10T00:00:00;
```

9.7.5   Occur [not] Within ... Following (ternary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR WITHIN <n:duration> FOLLOWING <n:times>
false := query_result OCCURRED WITHIN 3 days FOLLOWING 1990-03-10T00:00:00;
```

9.7.6   Occur [not] Within . . . Surrounding (ternary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR WITHIN <n:duration> SURROUNDING <n:times>
false := query_result OCCURRED WITHIN 3 days SURROUNDING 1990-03-10T00:00:00;
false := request occurred within 2 hours surrounding 14:00
(true, true, true, false, true) := measurements occurred within 30 minutes
    surrounding 13:00;
```

9.7.7   Occur [not] Within Past (binary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR WITHIN PAST <n:duration>
true := query_result OCCURRED WITHIN PAST 3 days;
```

9.7.8   Occur [not] Within Same Day As (binary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR WITHIN SAME DAY AS <n:time>
false := query_result OCCURRED WITHIN SAME DAY AS 1990-03-08T01:01:01;
null := query_result OCCURRED WITHIN SAME DAY AS 01:01:01;
```

9.7.9   Occur [not] Before (binary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR BEFORE <n:times>
true := query_result OCCURRED BEFORE 1990-03-08T01:01:01;
```

9.7.10   Occur [not] After (binary, non-associative)

```
<n:Boolean> := <n:any-type> OCCUR AFTER <n:times>
false := query_result OCCURRED AFTER 1990-03-08T01:01:01;
```

9.7.11   Occur [not] At (binary, non-associative)

The **occur at** operator functionally identical to the **occur equal** operator.

```
<n:Boolean> := <n:any-type> OCCUR AT <n:times>
false := query_result OCCURRED AT 1990-03-01T00:00:00;
```

See Section 9.7.2.

9.8   String Operators

The string operators do not follow the default list handling or the default primary time handling.

9.8.1 || (binary, left-associative)

The || operator (string concatenation) converts its arguments to strings and then concatenates those strings together. The null data type is converted to the string **null** and then appended to the other argument. Thus || never returns **null**. Lists are converted to strings and then appended to the other argument; the list is enclosed in parentheses and the elements are separated by **,** with no separating blanks. The string representation of Booleans, numbers, times, and durations is location-specific to allow for the use of the native language. The **formatted with** operators **%s** operator is used to convert values to strings (see Section 9.8.2). The **string** operator is a generalization of the || operator (see Section 9.8.3), except that the

Print date: 10/4/2023

string operator does not do anything special for lists. The primary times of its arguments are lost. Its usage is:

```
<1:string> := <m:any-type> || <n:any-type>
"null3" := null || 3;
"45" := 4 || 5;
"4.7four" := 4.7 || "four";
"true" := true || "";
"3 days left" := 3 days || " left";
"on 1990-03-15T13:45:01" := "on " || 1990-03-15T13:45:01;
"list=(1,2,3)" := "list=" || (1, 2, 3);
```

9.8.2   Formatted With (binary, left-associative)

The **formatted with** operator allows a formatting string to be used for additional control over how data items are output. The formatting string is similar to the ANSI C language printf control string, with additional ability to format an Arden time. Its usage is

```
<string> := <data> formatted with <format_string>

"01::02::03" := (1, 2, 3) formatted with "%2.2d::%2.2d::%2.2d";

"The result was 10.61 mg"
:= 10.60528 formatted with "The result was %.2f mg";

"The date was Jan 10 1998"
:= 1998-01-10T17:25:00 formatted with "The date was %.2t";

"The year was 1998"
:= 1998-01-10T17:25:00 formatted with "The year was %.0t";

/* longer example */
a := "ten";
b := "twenty";
c := "thirty";
f := "%s, %s, %s or more";
"ten, twenty, thirty or more" := (a, b, c) formatted with f;
```

If **data** is a single item, it serves as the single parameter for format string substitution. If **data** is a list, the list is not formatted as a list. Instead, it is assumed to be a list of parameters for format string substitution. Parameters are substituted into the **format string** as described below, which becomes the result of the operation.

A format string consists of a literal string and typically contains 1 or more format specifications.

A format specification, which consists of optional and required fields, has the following form:

```
%[flags][width][.precision]type
```

Each field of the format specification is a single character or a number signifying a particular format option. The simplest format specification contains only the percent sign and a type character (for example, %s). If a percent sign is followed by a character that has no meaning as a format field, the character is not revised. For example, to print a percent-sign character, use %%.

Note that to retain compatibility with C language functions, several formatting type specifiers have been retained that will probably not be useful to the Arden MLM author. The most likely format specification types an MLM author will use are:

```
%c     (for outputting special characters)
%s     (string width control)
%d     (integer formatting)
%t     (time formatting)
%e     (floating point number formatting with exponent)
```

```
%f      (floating point number formatting without exponent)
%g      (floating point number formatting using %e or %f)
```

A complete description of supported types within the format specification can be found in Annex A5.

9.8.3   String ... (unary, right-associative)

The **string** operator expects a string or list of strings as its argument. It returns a single string made by concatenating all the elements, as the || operator (see Section 9.8.1). If the argument is an empty list, the result is the empty string (""). The element operator (Section 9.12.18) can be used to select certain items from the list. The primary times of its arguments are lost. Its usage is:

```
<1:string> := STRING <m:string>
<1:string> := STRING <m:list of strings>
"abc" := STRING ("a", "b", "c");
"abc" := STRING ("a", "bc");
"" := STRING ();
"edcba" := STRING REVERSE EXTRACT CHARACTERS "abcde";
```

9.8.4   Matches Pattern (binary, non-associative)

The effect of this operator is similar to the LIKE operator in SQL (ISO / IEC 9075). **Matches pattern** is used to determine whether or not a particular string matches a pattern. This operator expects two string arguments. The first argument is a string to be matched, and the second is the pattern used for matching. **Matches pattern** returns a Boolean value: true if the pattern of the second argument matches the first argument and false if it does not. The first argument also may be a list of strings, in which case the result is a list of Boolean values, each corresponding to the match between one string and the pattern of the second argument. If the arguments are not strings, null is returned. Matching is case-insensitive. The primary times of the arguments are lost.

The pattern of the second argument may be any legal string character. In addition, two wild-card characters may be used. The underscore (_) will match exactly any one character. The percent sign (**%**) will match 0 to arbitrarily many characters. In order to match one of the literal wild-card character, precede it with an escape (\) character.

```
<n:Boolean> := <n:string> MATCHES PATTERN <1:string>
true := "fatal heart attack" MATCHES PATTERN "%heart%";
false := "fatal heart attack" MATCHES PATTERN "heart";
true := "abnormal values" MATCHES PATTERN "%value_";
false := "fatal pneumonia" MATCHES PATTERN "%pulmonary%";
(true, false) := ("stunned myocardium", "myocardial infarction") MATCHES
    PATTERN "%myocardium";
true := "5%" MATCHES PATTERN "_\%";
```

9.8.5   Length   (unary, right-associative)

The **length** operator returns the number of characters in a string. Leading or trailing spaces are included in this calculation. Applying the **length** operator to an empty string returns zero, while the **length** of a non-string data type or an empty list is **null**. The **length** operator is different from the **count** operator (see Section 9.12.2), in that **length** is the number of characters in a single string, while **count** is the number of items in a list. Primary times are not preserved.

```
<n:number> := LENGTH [OF] <n:string>
          7 := LENGTH OF "Example";
         14 := LENGTH "Example String";
          0 := LENGTH "";
       null := LENGTH ();
       null := LENGTH OF null;
(8, 3, null) := LENGTH OF ("Negative", "Pos", 2);
```

9.8.6   Uppercase   (unary, right-associative)

The **uppercase** operator converts all lowercase characters in a string to uppercase. Non-lowercase characters, including numeric and punctuation characters, are not affected. The **uppercase** of a non-string data type or an empty list is null. Primary times are preserved.

```
                  <n:string> := UPPERCASE <n:string>
           "EXAMPLE STRING" := UPPERCASE "Example String";
                        "" := UPPERCASE "";
                      null := UPPERCASE null;
                      null := UPPERCASE ();
      ("5-HIAA", "POS", null) := uppercase ("5-Hiaa", "Pos", 2);
```

9.8.7   Lowercase (unary, right-associative)

The **lowercase** operator converts all uppercase characters in a string to lowercase. Non-uppercase characters, including numeric and punctuation characters, are not affected. The **lowercase** of a non-string data type or empty list is **null**. Primary times are preserved.

```
                  <n:string> := LOWERCASE <n:string>
           "example string" := LOWERCASE "Example String";
                        "" := LOWERCASE "";
                      null := LOWERCASE 12.8;
                      null := LOWERCASE null;
      ("5-hiaa", "pos", null) := LOWERCASE ("5-HIAA", "Pos", 2);
```

9.8.8   Trim [Left | Right] (unary, right-associative)

The **trim** operator removes leading and trailing white space from a string (see Section 7.1.20). The optional **left** or **right** modifier can be applied to remove leading or trailing white space respectively. Printable characters and embedded white space characters are not affected. The **trim** of a non-string data type or empty list is **null**. Primary times are preserved.

```
             <n:string> := TRIM [LEFT | RIGHT] <n:string>
              "example" := TRIM "  example  ";
                    "" := TRIM "";
                  null := TRIM ();
           "result:  " := TRIM LEFT  "  result:  ";
           "  result:" := TRIM RIGHT "  result:  ";
      ("5 N", "2 E", null) := TRIM (" 5 N", "2 E ", 2);
```

9.8.9   Find...[in] String...[starting at]... (ternary, right-associative)

The **find ... string** operator locates a substring within a target string, and returns a number that represents the starting position of the substring. **Find ... string** is similar to **matches pattern**, but returns a number (rather than a boolean), and does not support wildcards. **Find ... string** is case-sensitive, and returns a zero if the target string does not contain the exact substring. If either the substring or target is not a string data type, **null** is returned. Primary times are not preserved.

The optional modifier **starting at...** can be appended to the **find ... string** operator to control where the search for the substring begins. Omitting the modifier causes the search to begin at the first character of the string. The value following **starting at...** must be an integer, otherwise **null** is returned. If the value following **starting at...** is an integer beyond the length of the target string (i.e. less than 1 or greater than **length** target), zero is returned.

```
         <n:number> := FIND <1:string> [IN] STRING <n:string>
         <n:number> := FIND <1:string> [IN] STRING <n:string> [STARTING AT <n:number>]
                  3 := FIND "a" IN STRING "Example Here";
                  5 := FIND "ple" IN STRING "Example Here";
                  0 := FIND "s" IN STRING "Example Here";
               null := FIND 2 IN STRING "Example Here";
               null := FIND "a" STRING 510;
```

```
     (2, 0, 4) := FIND "t" STRING ("start", "meds", "halt");
             7 := FIND "e" IN STRING "Example Here" STARTING AT 1;
             1 := FIND "e" IN STRING LOWERCASE "Example Here" STARTING AT 1;
            10 := FIND "e" IN STRING "Example Here" STARTING AT 8;
            10 := FIND "e" IN STRING "Example Here" STARTING AT 10;
            12 := FIND "e" IN STRING "Example Here" STARTING AT 11;
             0 := FIND "e" IN STRING "Example Here" STARTING AT 13;
          null := FIND "e" IN STRING "Example Here" STARTING AT 1.5;
          null := FIND "e" IN STRING "Example Here" STARTING AT "x";
       (10, 12) := FIND "e" IN STRING "Example Here" STARTING AT (10, 11);
```

9.8.10 Substring … Characters [starting at …] from … (ternary, right-associative)

The **substring … characters [starting at …] from …** operator returns a substring of characters from a designated target string. This substring consists of the specified number of characters from the source string beginning with the starting position (either the first character of the string or the specified location within the string). For example **substring 3 characters starting at 2 from "Example"** would return "xam" – a 3 character string beginning with the second character in the source string "Example".

The target string must be a string data type, the starting location within the string must be a positive integer, and the number of characters to be returned must be an integer, or the operator returns **null**. If a starting position is specified, its value must be an integer between 1 and the length of the string, otherwise an empty string is returned. If the requested number of characters is greater than the length of the string, the entire string is returned. If a starting point is specified, and the requested number of characters is greater than the length of the string minus the starting point, the resulting string is the original string to the right of and including the starting position. If the number of characters requested is positive the characters are counted from left to right. If the number of characters requested is negative, the characters are counted from right to left. The characters in a substring are always returned in the order that they appear in the string. Default list handling is observed. Primary times are preserved.

```
            <n:string> := SUBSTRING <n:number> CHARACTERS [STARTING AT <n:number>]
                                    FROM <n:string>
                  "ab" := SUBSTRING 2 CHARACTERS FROM "abcdefg";
             "abcdefg" := SUBSTRING 100 CHARACTERS FROM "abcdefg";
                 "def" := SUBSTRING 3 CHARACTERS STARTING AT 4 FROM "abcdefg";
                "defg" := SUBSTRING 20 CHARACTERS STARTING AT 4 FROM "abcdefg";
                  null := SUBSTRING 2.3 CHARACTERS FROM "abcdefg";
                  null := SUBSTRING 2 CHARACTERS STARTING AT 4.7 FROM "abcdefg";
                  null := SUBSTRING 3 CHARACTERS STARTING AT "c" FROM "abcdefg";
                  null := SUBSTRING "b" CHARACTERS STARTING AT 4 FROM "abcdefg";
                  null := SUBSTRING 3 CHARACTERS STARTING AT 4 FROM 281471;
                   "d" := SUBSTRING 1 CHARACTERS STARTING AT 4 FROM "abcdefg";
                   "d" := SUBSTRING -1 CHARACTERS STARTING AT 4 FROM "abcdefg";
                 "bcd" := SUBSTRING -3 CHARCTERS STARTING AT 4 FROM "abcdefg";
                   "a" := SUBSTRING 1 CHARACTERS FROM "abcdefg";
                   "g" := SUBSTRING -1 CHARACTERS STARTING AT LENGTH OF "abcdefg"
                                    FROM "abcdefg";
     ("Pos", "Neg", null) := SUBSTRING 3 CHARACTERS FROM ("Positive", "Negative", 2);
```

Example: Determine the systolic and diastolic values of patient's blood pressure when observations (bp) are stored as strings like this: "98/72", "121/86", or "138/102".

```
bp := "121/86";
slash_pos := FIND "/" IN STRING bp;
systolic := SUBSTRING (slash_pos - 1) CHARACTERS FROM bp;
```

or

```
systolic := SUBSTRING -3 CHARACTERS STARTING AT (slash_pos - 1) FROM bp;

diastolic := SUBSTRING 3 CHARACTERS STARTING AT (slash_pos + 1) FROM bp;
```

or

```
diastolic := SUBSTRING (LENGTH of bp) CHARACTERS STARTING AT (slash_pos + 1)
    FROM bp;
```

9.8.11   Localized (unary, non-associative)

The **localized** operator returns a string that has been previously defined in the language slot of the MLM's resources category. The string is looked up by choosing the key/value pair defined in the language slot that matches the current language setting of the system which executes the MLM. The argument of the operator specifies the term that is used as key to lookup the value for one specific text resource.

Retrieving the current language setting is implementation specific. If the language cannot be retrieved or no language slot is defined for the current language, the default language of the resources category is used. If the term is not defined in the chosen language slot or if the argument is not a Term, **null** is returned.

According to the examples in Section 6.4.2 its usage is:

```
<n:string> := LOCALIZED <n:term>
    "Caution, the patient has
     the following allergy to
     penicillin documented: " := localized 'msg';
    "The patient's calculated
     creatinine clearance is
     0.33 ml/min."             := creat formatted with localized 'creat';
    null                       := localized 'unknown';
```

Or in a German setting:

```
    "Vorsicht, zu diesem Patienten
     wurde die folgende
     Penicillinallergie
     dokumentiert: "           := localized 'msg';
    "Die berechnete Kreatinin-
     Clearance des Patienten
     beträgt 0,33 ml/min."     := creat formatted with localized 'creat';
    null                       := localized 'unknown';
```

9.8.12   Localized (binary, right-associative)

The binary **localized** operator acts like the unary version of this operator and additionally allows the selection of the target language as second argument. As second operator, either a string constant or a variable can be used. Other expressions are not valid.

This operator can be used if the language of the message has to be different from the current language in the system setting, for example when the system language is English (as the user operates in an English environment), but the recipient of the message text requires another language, such as German.

Regarding the lookup mechanism and the default language handling it acts in the same way like the unary version. In addition, if the second argument does not resolve to a string, the default language is used. Its usage is:

```
<n:string> := LOCALIZED <n:term> by <n:string>
    "Caution, the patient has
     the following allergy to
     penicillin documented: " := localized 'msg' by "en_US";
    "Die berechnete Kreatinin-
     Clearance des Patienten
     beträgt 0,33 ml/min."   := creat formatted with localized 'creat' by
                                      lang_setting;      /* lang_setting == "de" */
```

9.9   Arithmetic Operators

The behavior of time and duration data types is explained in Section 8.5.2.

9.9.1   + (binary, left-associative)

Binary + (addition) adds the left and right arguments. It can perform simple addition, add two durations, or increment a time by a duration. Underflow or overflow results in **null**. Its usage is:

```
<n:number> := <n:number> + <n:number>
   6 := 4 + 2;
   () := 5 + ();
   null := (1,2,3) + ();
   () := null + ();
   null := 5 + null;
   (null, null, null) := (1, 2, 3) + null;
   null := null + null;
<n:duration> := <n:duration> + <n:duration>
   3 days := 1 day + 2 days;
<n:times> := <n:times> + <n:duration>
   1990-03-15T00:00:00 := 1990-03-13T00:00:00 + 2 days;
   1993-05-17T00:00:00 := 0000-00-00 + 1993 years + 5 months + 17 days;
<n:times> := <n:duration> + <n:times>
   1990-03-15T00:00:00 := 2 days + 1990-03-13T00:00:00;
```

9.9.2   + (unary, non-associative)

Unary + has no effect on its argument if it is of a valid type. Its usage is:

```
<n:number> := + <n:number>
   2 := + 2;
   null := + "asdf";
<n:duration> := + <n:duration>
   2 days := + 2 days;
```

9.9.3   - (binary, left-associative)

Binary **-** (subtraction) subtracts the right argument from the left. It can perform numeric subtraction, subtract two durations, decrement a time by a duration, or find the duration between two times. Underflow or overflow results in **null**. In writing expressions, care must be taken that the subtraction operator is not confused with the "-" in time constant (Section 7.1.9). Any ambiguity is resolved in favor of time constants. Its usage is:

```
<n:number> := <n:number> - <n:number>
   4 := 6 - 2;
<n:duration> := <n:duration> - <n:duration>
   1 day := 3 days - 2 days;
<n:times> := <n:times> - <n:duration>
   1990-03-13T00:00:00 := 1990-03-15T00:00:00 - 2 days;
<n:duration> := <n:times> - <n:times>
   2 days := 1990-03-15T00:00:00 - 1990-03-13T00:00:00;
```

9.9.4   - (unary, non-associative)

Unary **-** is used for arithmetic negation; this is how one makes negative number constants. Underflow or overflow results in **null**. One cannot put two arithmetic operators together, so the following expression is illegal: **3 + -4**. Instead one must use one of these: **3 + (-4)**, **3 - 4**, or **-4 + 3**. Its usage is:

```
<n:number> := - <n:number>
   (-2) := - 2;
<n:duration> := - <n:duration>
   (-2) days := - (2 days);
```

9.9.5   ***** (binary, left-associative)

The ***** operator (multiplication) multiplies the left and right arguments. Underflow or overflow results in **null**. It can perform numeric multiplication or multiply a duration by a number. Its usage is:

```
<n:number> := <n:number> * <n:number>
   8 := 4 * 2;
<n:duration> := <n:number> * <n:duration>
   6 days := 3 * 2 days;
<n:duration> := <n:duration> * <n:number>
   6 days := 2 days * 3;
```

9.9.6   **/** (binary, left-associative)

The / operator (division) divides the left argument by the right one. It can perform numeric division, divide a duration by a number, or find the ratio between two durations. **Null** results from division by zero, underflow, or overflow. Duration unit conversion can be done with the / operator (e.g., **…** / **1 year** turns any duration into years). Its usage is:

```
<n:number> := <n:number> / <n:number>
   4 := 8 / 2;
<n:duration> := <n:duration> / <n:number>
   2 days := 6 days / 3;
<n:number> := <n:duration> / <n:duration>
   120 := 2 minutes / 1 second;
   36 := 3 years / 1 month;
```

9.9.7   ****** (binary, non-associative)

The ****** operator (exponentiation) raises the left argument to the power of the right argument. Its usage is:

```
<n:number> := <n:number> ** <1:number>
   9 := 3 ** 2;
```

9.10   Temporal Operators

The behavior of time and duration data types is explained in Section 8.5.2.

9.10.1   After (binary, non-associative)

The **after** operator is equivalent to addition between a duration and a time. Its usage is:

```
<n:times> := <n:duration> AFTER <n:times>
   1990-03-15T00:00:00 := 2 days AFTER 1990-03-13T00:00:00;
```

9.10.2   Before (binary, non-associative)

The **before** operator is equivalent to the subtraction of a duration from a time. Its usage is:

```
<n:times> := <n:duration> BEFORE <n:times>
   1990-03-11T00:00:00 := 2 days BEFORE 1990-03-13T00:00:00;
```

9.10.3   Ago (unary, non-associative)

The **ago** operator subtracts a duration from **now**, resulting in a time. Its usage is (assuming that **now** is 1990-04-19T00:03:15):

```
<n:time> := <n:duration> AGO
   1990-04-17T00:03:15 := 2 days AGO;
```

9.10.4 From (binary, non-associative)

The **from** operator is equivalent to addition between a duration and a time. Its usage is:

```
<n:times> := <n:duration> FROM <n:times>
    2000-09-13T00:08:00 := 2 days FROM 2000-09-11T00:08:00;
```

9.10.5 Time of Day [of] (unary, right-associative)

The **time of day** operator extracts the time-of-day from a time. Primary times are lost.
Its usage is:

```
<n:time-of-day> := TIME OF DAY [OF] <n:time>
    14:23:17.3 := TIME OF DAY OF 1990-01-03T14:23:17.3;
    null := TIME OF DAY OF "this is not a time";
    /* let time of data0 be 2006-01-01T12:00:00 */
    12:00:00 := TIME OF DAY OF (TIME OF data0);
    null := TIME OF (TIME OF DAY OF (TIME OF data0));
```

9.10.6 Day of Week [of] (unary, right-associative)

The **day of week** operator returns a positive integer from 1 to 7 that represents the day of the week of a specified time (Section 8.12). The number 1 corresponds to Monday, 2 corresponds to Tuesday, etc. The number 7 represents Sunday. This operator may be used with a user-defined list of strings to report an actual weekday in an appropriate language, or may be used with the reserved words representing the days of the week. The example below assumes that 2006-05-26 was a Friday, 2006-06-03 was a Sunday, 2006-06-06 was a Tuesday, **potassium** is the result of a query with the primary times (2006-06-03T09:04:00, 2006-06-06T16:40:00), and the weekday of now is a Monday.

```
<n:number> := DAY OF WEEK [OF] <n:time>
    5 := DAY OF WEEK OF 2006-05-26T13:20:00;
    (6, 2) := DAY OF WEEK OF (TIME OF potassium);
    1 := DAY OF WEEK OF now;
    null := DAY OF WEEK 15:30:00;
    true := DAY OF WEEK OF 2006-05-26T13:20:00 = FRIDAY;
    (true, false) := DAY OF WEEK OF TIME OF potassium IS IN (SATURDAY,
     SUNDAY);
    false := DAY OF WEEK OF now IS IN (SATURDAY, SUNDAY);
```

A more detailed example:

```
weekend := DAY OF WEEK OF eventtime is in (SATURDAY, SUNDAY);
// weekend is true if the event occurred on Saturday or Sunday
weekday := ("Monday", "Tuesday", …, "Sunday");
last_k := last potassium;
last_k_time := time last_k;
msg := "The last potassium was collected on "
 || weekday[DAY OF WEEK OF last_k_time];
//"The last potassium was collected on Tuesday"
```

9.10.7 Extract Year (unary, right-associative)

The **extract year** operator extracts the year from a time. Its usage is:

```
<n:number> := EXTRACT YEAR <n:time>
    1990 := EXTRACT YEAR 1990-01-03T14:23:17.3;
    null := EXTRACT YEAR (1 YEAR);
    null := EXTRACT YEAR 14:23:17.3;
```

9.10.8 Extract Month (unary, right-associative)

The **extract month** operator extracts the month from a time. Its usage is:

```
<n:number> := EXTRACT MONTH <n:time>
    1 := EXTRACT MONTH 1990-01-03T14:23:17.3;
```

```
null := EXTRACT MONTH 1;
null := EXTRACT MONTH 14:23:17.3;
```

9.10.9 Extract Day (unary, right-associative)

The **extract day** operator extracts the day from a time. Its usage is:

```
<n:number> := EXTRACT DAY <n:time>
    3 := EXTRACT DAY 1990-01-03T14:23:17.3;
    null := EXTRACT DAY "this is not a time";
    null := EXTRACT DAY 14:23:17.3;
```

9.10.10 Extract Hour (unary, right-associative)

The **extract hour** operator extracts the hour from a time. Its usage is:

```
<n:number> := EXTRACT HOUR <n:times>
    14 := EXTRACT HOUR 1990-01-03T14:23:17.3;
    null := EXTRACT HOUR (1 HOUR);
    14 := EXTRACT HOUR 14:23:17.3;
```

9.10.11 Extract Minute (unary, right-associative)

The **extract minute** operator extracts the minute from a time. Its usage is:

```
<n:number> := EXTRACT MINUTE <n:times>
    23 := EXTRACT MINUTE 1990-01-03T14:23:17.3;
    0 := EXTRACT MINUTE 1990-01-03;
    null := EXTRACT MINUTE 0000-00-00;
    23 := EXTRACT MINUTE 14:23:17.3;
```

9.10.12 Extract Second (unary, right-associative)

The **extract second** operator extracts the second from a time. Its usage is:

```
<n:number> := EXTRACT SECOND <n:times>
    17.3 := EXTRACT SECOND 1990-01-03T14:23:17.3;
    null := EXTRACT SECOND (1 second);
    17.3 := EXTRACT SECOND 14:23:17.3;
```

9.10.13 Replace Year [of] … With (binary, right-associative)

The **replace year of … with** operator allows the replacement of the year part of a time. The result of the **replace year of … with** operator preserves the primary time of the first argument. The numeric second argument must evaluate to a positive integer greater than or equal to 1800, otherwise **null** is returned. Any fractional part of the second argument will be removed before evaluation. For example:

```
<n:time> := REPLACE YEAR [OF] <n:time> WITH <n:number>
    var1 := 1990-03-15T15:00:00;
    2011-03-15T15:00:00 := REPLACE YEAR OF var1 WITH 2011;
    (2011-03-15T15:00:00, 2010-03-15T15:00:00) := REPLACE YEAR OF var1 WITH
     (2011, 2010);
    null := REPLACE YEAR OF var1 WITH -10;
    null := REPLACE YEAR OF var1 WITH "7";
    var2 := 19:00:00;
    null := REPLACE YEAR OF var2 WITH 2011;
    var3 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
    (2011-09-21T16:30:00, 2011-03-15T15:00:00) := REPLACE YEAR OF var3 WITH
     2011;
    var3 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
    (1999-09-21T16:30:00, 2000-03-15T15:00:00) := REPLACE YEAR OF var3 WITH
     (1999, 2000);
    null := REPLACE YEAR OF var3 WITH (1999, 2000, 2002);
```

9.10.14 Replace Month [of] … With (binary, right-associative)

The **replace month of … with** operator allows the replacement of the month part of a time. The result of the **replace month of … with** operator preserves the primary time of the first argument. The numeric second argument must evaluate to a positive integer between 1 and 12, otherwise **null** is returned. Any fractional part of the second argument will be removed before evaluation. For example:

```
<n:time> := REPLACE MONTH [OF] <n:time> WITH <n:number>
  var1 := 1990-03-15T15:00:00;
  1990-11-15T15:00:00 := REPLACE MONTH OF var1 WITH 11;
  (1990-11-15T15:00:00, 1990-10-15T15:00:00) := REPLACE MONTH OF var1 WITH
   (11, 10);
  null := REPLACE MONTH OF var1 WITH 14;
  null := REPLACE MONTH OF var1 WITH "7";
  1990-07-15T15:00:00 := REPLACE MONTH OF var1 WITH 7.45;
  var2 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
  (2010-12-21T16:30:00, 2010-12-15T15:00:00) := REPLACE MONTH OF var2 WITH
   12;
  var3 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
  (2010-06-21T16:30:00, 2010-07-15T15:00:00) := REPLACE MONTH OF var3 WITH
   (6, 7);
  null := REPLACE MONTH OF var3 WITH (3, 4, 7);
```

9.10.15 Replace Day [of] …With (binary, right-associative)

The **replace day of … with** operator allows the replacement of the day part of a time. The result of the **replace day of … with** operator preserves the primary time of the first argument. The numeric second argument must evaluate to a positive integer between 1 and the number of days in the existing month of the first operator, otherwise, **null** is returned. Any fractional part of the second argument will be removed before evaluation. For example:

```
<n:time> := REPLACE DAY [OF] <n:time> WITH <n:number>
  var1 := 1990-03-15T15:00:00;
  1990-03-11T15:00:00 := REPLACE DAY OF var1 WITH 11;
  (1990-03-11T15:00:00, 1990-03-10T15:00:00) := REPLACE DAY OF var1 WITH
   (11, 10);
  null := REPLACE DAY OF var1 WITH 100;
  null := REPLACE DAY OF var1 WITH "7";
  1990-03-07T15:00:00 := REPLACE DAY OF var1 WITH 7.45;
  null := REPLACE DAY OF 1990-02-11T15:00:00 WITH 30;
  null := REPLACE DAY OF 1990-02-11T15:00:00 WITH 0.8;
  1990-02-01T15:00:00:= REPLACE DAY OF 1990-02-15T15:00:00 WITH 1.8;
  var2 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
  (2010-09-07T16:30:00, 2010-03-07T15:00:00) := REPLACE DAY OF var2 WITH 7;
  var3 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
  (2010-09-12T16:30:00, 2010-03-23T15:00:00) := REPLACE DAY OF var3 WITH
   (12, 23);
  null := REPLACE DAY OF var3 WITH (12, 23, 24);
```

9.10.16 Replace Hour [of] … With (binary, right-associative)

The **replace hour of … with** operator allows the replacement of the hour part of a time or time-of-day. The result of the **replace hour of … with** operator preserves the primary time of the first argument. The numeric second argument must evaluate to a positive integer between 0 and 23, otherwise, **null** is returned. Any fractional part of the second argument will be removed before evaluation. For example:

```
<n:times> := REPLACE HOUR [OF] <n:times> WITH <n:number>
  var1 := 1990-03-15T15:00:00;
  1990-03-15T11:00:00 := REPLACE HOUR OF var1 WITH 11;
  (1990-03-15T11:00:00, 1990-03-15T10:00:00) := REPLACE HOUR OF var1 WITH
   (11, 10);
  null := REPLACE HOUR OF var1 WITH 100;
```

```
null := REPLACE HOUR OF var1 WITH "7";
10:00 := REPLACE HOUR OF 18:00 WITH 10;
var2 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
(2010-09-21T20:30:00, 2010-03-15T20:00:00) := REPLACE HOUR OF var2 WITH
 20;
var3 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
(2010-09-21T07:30:00, 2010-03-15T09:00:00) := REPLACE HOUR OF var3 WITH
 (7, 9);
null := REPLACE HOUR OF var3 WITH (7, 9, 13);
```

9.10.17 Replace Minute [of] … With (binary, right-associative)

The **replace minute of … with** operator allows the redefinition of the minute part of a time or time-of-day. The result of the **replace minute of … with** operator preserves the primary time of the first argument. The numeric second argument must evaluate to a positive integer between 0 and 59, otherwise, **null** is returned. Any fractional part of the second argument will be removed before evaluation. For example:

```
<n:times> := REPLACE MINUTE [OF] <n:times> WITH <n:number>
var1 := 1990-03-15T15:00:00;
1990-03-15T15:11:00 := REPLACE MINUTE OF var1 WITH 11;
(1990-03-15T15:11:00, 1990-03-15T15:10:00) := REPLACE MINUTE OF var1 WITH
 (11, 10);
null := REPLACE MINUTE OF var1 WITH 100;
null := REPLACE MINUTE OF var1 WITH "7";
18:10 := REPLACE MINUTE OF 18:00 WITH 10;
var2 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
(2010-09-21T16:15:00, 2010-03-15T15:15:00) := REPLACE MINUTE OF var2 WITH
 15;
var3 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
(2010-09-21T16:25:00, 2010-03-15T15:23:00) := REPLACE MINUTE OF var3 WITH
 (25, 23);
null := REPLACE MINUTE OF var3 WITH (25, 23, 7);
```

9.10.18 Replace Second [of] … With (binary, right-associative)

The **replace second of … with** operator allows the redefinition of the second part of a time or time-of-day. The result of the **replace second of … with** operator preserves the primary time of the first argument. The numeric second argument must be a positive number greater than or equal to 0 and strictly lower than 60, otherwise, **null** is returned. Fractional replacement parameters are allowed for the **replace second of … with** operator. For example:

```
<n:times> := REPLACE SECOND [OF] <n:times> WITH <n:number>
var1 := 1990-03-15T15:00:00;
1990-03-15T15:00:11 := REPLACE SECOND OF var1 WITH 11;
(1990-03-15T15:00:11, 1990-03-15T15:00:10) := REPLACE SECOND OF var1 WITH
 (11, 10);
null := REPLACE SECOND OF var1 WITH -100;
null := REPLACE SECOND OF var1 WITH "7";
18:00:10 := REPLACE SECOND OF 18:00 WITH 10;
var2 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
(2010-09-21T16:30:33, 2010-03-15T15:00:33) := REPLACE SECOND OF var2 WITH
 33;
var3 := (2010-09-21T16:30:00, 2010-03-15T15:00:00);
(2010-09-21T16:30:23, 2010-03-15T15:00:42) := REPLACE SECOND OF var3 WITH
 (23, 42);
null := REPLACE SECOND OF var3 WITH (23, 42, 55);
```

9.11 Duration Operators

The behavior of the duration data type is explained in Section 8.5.2. Because the precedence of the temporal operators is lower than that of the duration operators, **3 hours before 3 days ago** is parsed as **(3**

hours) before ((3 days) ago), and it would return what time it was three days and three hours before the current time.

9.11.1 Year (unary, non-associative)

The **year** operator has one synonym: **years**. It creates a months duration from a number: one year is 12 months. Its usage is:

```
<n:duration> := <n:number> YEAR
   24 months := 2 YEAR;
```

9.11.2 Month (unary, non-associative)

The **month** operator has one synonym: **months**. It creates a months duration from a number. Its usage is:

```
<n:duration> := <n:number> MONTH
```

9.11.3 Week (unary, non-associative)

The **week** operator has one synonym: **weeks**. It creates a seconds duration from a number: one week is 604800 seconds. Its usage is:

```
<n:duration> := <n:number> WEEK
```

9.11.4 Day (unary, non-associative)

The **day** operator has one synonym: **days**. It creates a seconds duration from a number: one day is 86400 seconds. Its usage is:

```
<n:duration> := <n:number> DAY
```

9.11.5 Hour (unary, non-associative)

The **hour** operator has one synonym: **hours**. It creates a seconds duration from a number: one hour is 3600 seconds. Its usage is:

```
<n:duration> := <n:number> HOUR
```

9.11.6 Minute (unary, non-associative)

The **minute** operator has one synonym: **minutes**. It creates a seconds duration from a number: one minute is 60 seconds. Its usage is:

```
<n:duration> := <n:number> MINUTE
```

9.11.7 Second (unary, non-associative)

The **second** operator has one synonym: **seconds**. It creates a seconds duration from a number. Its usage is:

```
<n:duration> := <n:number> SECOND
```

9.12 Aggregation Operators

9.12.1 General Properties

The aggregation operators do not follow the default list handling, or the default primary time handling. They perform aggregation on a list. That is, they take a list as an argument (they are all unary) and return a single item as a result. Unless otherwise noted, if all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). An argument that is a single item is treated as a list of length one.

Each of the operators may be followed by the word **of**. Parentheses are not required. For example, these are all the same:

```
SUM a_list
SUM OF a_list
```

```
SUM(a_list)
SUM OF(a_list)
```

Multiple aggregation and transformation operators (for example, see Section 9.14) may be placed in an expression without parentheses; for example:

```
AVERAGE OF LAST 3 FROM a_list
```

9.12.2 Count (unary, right-associative)

The **count** operator returns the number of items (including null items) in a list. **Count** never returns **null**. The result loses the primary time. Its usage is:

```
<1:number> := COUNT <n:any-type>
    4 := COUNT (12, 13, 14, null)
    1 := COUNT "asdf"
    0 := COUNT ()
    1 := COUNT null
```

9.12.3 Exist (unary, right-associative)

The **exist** operator has one synonym: **exists**. It returns **true** if there is at least one non-null item in a list of any type. If the list argument is a single item, then it is treated as a list of length one. **Exist** never returns **null**. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). Its usage is:

```
<1:Boolean> := EXIST <n:any-type>
    true := EXIST (12, 13, 14);
    false := EXIST null;
    false := EXIST ();
    true := EXIST ("plugh", null);
```

9.12.4 Average (unary, right-associative)

The **average** operator has one synonym: **avg**. It calculates the average of a number, time, or duration list. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). Its usage is:

```
<1:number> := AVERAGE <n:number>
    14 := AVERAGE (12, 13, 17);
    3 := AVERAGE 3;
    null := AVERAGE ();
<1:time> := AVERAGE <n:times>
    1990-03-11T03:10:00 := AVERAGE (1990-03-10T03:10:00, 1990-03-12T03:10:00);
    null := AVERAGE (03:10:00, 1990-03-12T03:10:00);
    04:10:00 := AVERAGE (03:10:00, 05:10:00);
<1:duration> := AVERAGE <n:duration>
    3 days := AVERAGE (2 days, 3 days, 4 days);
```

9.12.5 Median (unary, right-associative)

The **median** operator calculates the median value of a number, time, or duration list. The list is first sorted. If there is an odd number of items, it selects the middle value. If there is an even number of items, it averages the middle two values. If there is a tie, then it selects the latest of those elements that have a primary time. If a single element is selected or if the two selected elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). Its usage is:

```
<1:number> := MEDIAN <n:number>
    13 := MEDIAN (12, 17, 13);
    3 := MEDIAN 3;
    null := MEDIAN ();
<1:times> := MEDIAN <n:times>
```

```
             1990-03-11T03:10:00 := MEDIAN (1990-03-10T03:10:00, 1990-03-11T03:10:00,
              1990-03-28T03:10:00);
             03:10:00 := MEDIAN (03:10:00, 02:10:00, 23:10:00);
         <1:duration> := MEDIAN <n:duration>
             3 days := MEDIAN (1 hour, 3 days, 4 years);
```

9.12.6 Sum (unary, right-associative)

The **sum** operator calculates the sum of a number or duration list. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). Its usage is:

```
         <1:number> := SUM <n:number>
             39 := SUM (12, 13, 14);
             3 := SUM 3;
             0 := SUM ();
         <1:duration> := SUM <n:duration>
             7 days := SUM (1 day, 6 days);
```

9.12.7 Stddev (unary, right-associative)

The **stddev** operator returns the sample standard deviation of a numeric list. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). Its usage is:

```
         <1:number> := STDDEV <n:number>
             1.58113883 := STDDEV (12, 13, 14, 15, 16);
             null := STDDEV 3;
             null := STDDEV ();
```

9.12.8 Variance (unary, right-associative)

The **variance** operator returns the sample variance of a numeric list. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). Its usage is:

```
         <1:number> := VARIANCE <n:number>
             2.5 := VARIANCE (12, 13, 14, 15, 16);
             null := VARIANCE 3;
             null := VARIANCE ();
```

9.12.9 Minimum (unary, right-associative)

The **minimum** operator has one synonym: **min**. It returns the smallest value in a homogeneous list of an ordered type (that is, all numbers, all times, all durations, or all strings), using the **<=** operator (see Section 9.5.4). If there is a tie, it selects the element with the latest primary time. The primary time of the selected argument is maintained. Its usage is:

```
         <1:ordered> := MINIMUM <n:ordered>
             12 := MINIMUM (12, 13, 14);
             3 := MIN 3;
             null := MINIMUM ();
             null := MINIMUM (1, "abc");
```

The **minimum** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the minimum. For example:

```
         <1:object> := minimum <n:object> using it.age; // will return the youngest
                                // person from a list of persons (represented by objects)
             180 := minimum (0, 30, 90, 180, 200, 300) using cosine of it;
```

9.12.10 Maximum (unary, right-associative)

The **maximum** operator has one synonym: **max**. It returns the largest value in a homogeneous list of an ordered type, using the **>=** operator (see Section 9.5.6). If there is a tie, it selects the element with the latest primary time. The primary time of the selected argument is maintained. Its usage is:

```
<1:ordered> := MAXIMUM <n:ordered>
   14 := MAXIMUM (12, 13, 14);
   3 := MAXIMUM 3;
   null := MAXIMUM ();
   null := MAXIMUM (1,"abc");
```

The **maximum** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the maximum. For example:

```
<1:object> := maximum <n:object> using it.age; // will return the oldest
                          // person from a list of persons (represented by objects)
   90 := maximum (0, 30, 90, 180, 200, 300) using sinus of it;
```

9.12.11 Last (unary, right-associative)

The **last** operator returns the value at the end of a list, regardless of type. If the list is empty, **null** is returned. The expression **last x** is equivalent to **x[count x]**. **Last** on the result of a time-sorted query will return the most recent value. The primary time of the selected argument is maintained. Note that **last** is different than **last** specified in Arden Syntax version E 1460-92. That operator is now called **latest** (see Section 9.12.16). Its usage is:

```
<1:any-type> := LAST <n:any-type>
   14 := LAST (12, 13, 14);
   3 := LAST 3;
   null := LAST ();
```

9.12.12 First (unary, right-associative)

The **first** operator returns the value at the beginning of a list. If the list is empty, **null** is returned. The expression **first x** is equivalent to **x[1]**. **First** on the result of a time-sorted query will return the earliest value. The primary time of the selected argument is maintained. Note that **first** is different than **first** specified in Arden Syntax version E 1460-92. That operator is now called **earliest** (see Section 9.12.17). Its usage is:

```
<1:any-type> := FIRST <n:any-type>
   12 := FIRST (12, 13, 14);
   3 := FIRST 3;
   null := FIRST ();
```

9.12.13 Any [IsTrue] (unary, right-associative)

The **any** operator returns **true** if any of the items in a list is **true**. It returns **false** if they are all **false**. Otherwise it returns **null**. The special case of a list with zero members, results in false. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). The optional keyword "**IsTrue**" can be used to increase the readability of statements using the **any** operator. Its usage is:

```
<1:Boolean> := ANY [ISTRUE] <n:any-type>
   true := ANY IsTrue (true, false, false);
   false := ANY false;
   false := ANY ();
   null := ANY (3, 5, "red");
   false := ANY (false, false);
   null := ANY (false, null);
```

9.12.14 All [AreTrue] (unary, right-associative)

The **all** operator returns **true** if all of the items in a list are **true**. It returns **false** if any of the items is **false**. Otherwise it returns **null**. The special case of a list with zero members, results in true. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). The optional keyword "**AreTrue**" can be used to increase the readability of statements using the **all** operator. Its usage is:

```
<1:Boolean> := ALL [ARETRUE] <n:any-type>
    false := ALL AreTrue (true, false, false);
    false := ALL false;
    true := ALL ();
    null := ALL (3, 5, "red");
    null := ALL (true, null);
```

9.12.15 No [IsTrue] (unary, right-associative)

The **no** operator returns **true** if all of the items in a list are **false**. It returns **false** if any of the items is **true**. Otherwise it returns **null**. The special case of a list with zero members, results in true. If all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time is lost). The optional keyword "**IsTrue**" can be used to increase the readability of statements using the **no** operator. Its usage is:

```
<1:Boolean> := NO [ISTRUE] <n:any-type>
    false := NO IsTrue (true, false, false);
    true := NO false;
    true := NO ();
    null := NO (3, 5, "red");
    null := NO (false, null);
```

9.12.16 Latest (unary, right-associative)

The **latest** operator returns the value with the latest primary time in a list. If any of the elements do not have primary times, the result is **null** (the argument can always be qualified by **where time of it is present**, if this is not desired behavior). If the list is empty, **null** is returned. If more than one element has the latest primary time, the first (with the lowest index) of these elements will be returned. The primary time of the selected argument is maintained. Its usage is:

```
<1:any-type> := LATEST <n:any-type>
    null := LATEST ();
"penicillin" := LATEST ("penicillin", "ibuprofen", "pseudoephedrine HCL");
   (T16:40)            (T16:40)        (T14:05)          (T14:04)
```

The **latest** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the latest value. For example:

```
<1:object> := latest <n:object> using it.birthday; //will return the youngest
                      // person from a list of persons (represented by objects)
```

9.12.17 Earliest (unary, right-associative)

The **earliest** operator returns the value with the earliest primary time in a list. If any of the elements do not have primary times, the result is **null** (the argument can always be qualified by **where time of it is present**, if this is not desired behavior). If more than one element has the earliest primary time, the first (with the lowest index) of these elements will be returned. If the list is empty, **null** is returned. The primary time of the argument is maintained. Its usage is:

```
<1:any-type> := EARLIEST <n:any-type>
        null := EARLIEST ();
"pseudoephedrine HCL" := EARLIEST ("penicillin", "ibuprofen", "pseudoephedrine HCL");
      (T14:04)                        (T16:40)        (T14:05)          (T14:04)
```

The **earliest** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the earliest value. For example:

```
<1:object> := earliest <n:object> using it.birthday; //will return the
                // youngest person from a list of persons (represented by objects)
```

9.12.18   Element (binary)

The element (**[…]**) operator is used to select one or more elements from a list, based on ordinal position starting at 1 for the first element. The arguments to "index" are a list expression (to the left of the **[…]**) and a list of integers (inside the**[…]**). The element operator maintains the primary times of the selected arguments. Its usage is:

```
<n:any-type> := <k:any-type>[n:index]
   20 := (10, 20, 30, 40)[2];
   () := (10, 20)[()];
   (null, 20) := (10, 20)[1.5, 2];
   (10, 30, 50) := (10, 20, 30, 40, 50)[1, 3, 5];
   (10, 30, 50) := (10, 20, 30, 40, 50)[1, (3, 5)];
   (10, 20, 30) := (10, 20, 30, 40, 50)[1 seqto 3];
```

9.12.19   Extract Characters ... (unary, right-associative)

The **extract characters** operator expects a string as its argument. It returns a list of the single characters in the string. If the argument has more than one element, the elements are first concatenated, as for the || operator (see Section 9.8.1). If the argument is an empty list, the result is the empty list **()**. The **string** operator (Section 9.8.3) can be used to put the list back together; and the index operator (Section 9.12.18) can be used to select certain items from the list. The primary times of its arguments are lost. Its usage is:

```
<n:string> := EXTRACT CHARACTERS <m:string>
   ("a", "b", "c") := EXTRACT CHARACTERS "abc";
   ("a", "b", "c") := EXTRACT CHARACTERS ("ab", "c");
   () := EXTRACT CHARACTERS ();
   () := EXTRACT CHARACTERS "";
   "edcba" := STRING REVERSE EXTRACT CHARACTERS "abcde";
```

9.12.20   Seqto (binary, non-associative)

The **seqto** operator generates a list of integers in ascending order. Both arguments must be single integers; otherwise null is returned. If the first argument is greater than the second argument, the result is the empty list. The primary times are lost. Its usage is:

```
<n:number> := <1:number> SEQTO <1:number>
   (2, 3, 4) := 2 SEQTO 4;
   () := 4 SEQTO 2;
   null := 4.5 SEQTO 2;
   (2) := 2 SEQTO 2;
   (-3, -2, -1) := (-3) SEQTO (-1);
   (2, 4, 6, 8) := 2 * (1 SEQTO 4);
   null := (1.5 seqto 5);
```

9.12.21   Reverse (unary, right-associative)

The **reverse** operator generates a new list with the elements in the reverse order. The primary times of its arguments are maintained. Its usage is:

```
<n:any-type> := REVERSE <n:any-type>
   (3, 2, 1) := reverse (1, 2, 3);
   (6, 5, 4, 3, 2, 1) := reverse (1 seqto 6);
   () := reverse ();
```

9.12.22   Index Extraction Aggregation Operators

These operators behave similarly to their non-index extracting counterparts with the exception that they return the value of the index of the element that matches the specified criteria rather than the value of the element. These operators do not maintain primary times.

9.12.22.1 *Index Latest (unary, right-associative)*

The **index latest** operator returns the index of the element with the latest primary time in a list. If any of the elements do not have primary times, the result is **null** (the argument can always be qualified by **where time of it is present**, if this is not desired behavior). If the list is empty, **null** is returned. The primary time of the selected argument is maintained. Its usage is:

```
<1:any-type> := INDEX LATEST <n:any-type>
   null := INDEX LATEST ();

1 := INDEX LATEST ("penicillin", "ibuprofen", "pseudophedrine HCL");
                      (T16:40)      (T14:05)          (T14:04)
```

9.12.22.2 *Index Earliest (unary, right-associative)*

The **index earliest** operator returns the index of the element with the earliest primary time in a list. If any of the elements do not have primary times, the result is **null** (the argument can always be qualified by **where time of it is present**, if this is not desired behavior). If the list is empty, **null** is returned. The primary time of the argument is maintained. Its usage is:

```
<1:any-type> := INDEX EARLIEST <n:any-type>
   null := INDEX EARLIEST ()

3 := INDEX EARLIEST ("penicillin", "ibuprofen", "pseudophedrine HCL");
                        (T16:40)      (T14:05)          (T14:04)
```

9.12.22.3 *Index Minimum (unary, right-associative)*

The **index minimum** operator has one synonym: **index min**. It returns the index of the element with the smallest value in a homogeneous list of an ordered type (that is, all numbers, all times, all durations, or all strings), using the <= operator (see Section 9.5.4). If there is a tie, it selects the element with the latest primary time. Its usage is:

```
<1:ordered> := INDEX MINIMUM <n:ordered>
   1 := INDEX MINIMUM (12, 13, 14);
   1 := INDEX MIN 3;
   null := INDEX MINIMUM ();
   null := INDEX MINIMUM (1, "abc");
```

9.12.22.4 *Index Maximum (unary, right-associative)*

The **index maximum** operator has one synonym: **index max**. It returns the largest value in a homogeneous list of an ordered type, using the >= operator (see Section 9.5.6). If there is a tie, it selects the element with the latest primary time. The primary time of the selected argument is maintained. Its usage is:

```
<1:ordered> := INDEX MAXIMUM <n:ordered>
   3 := INDEX MAXIMUM (12, 13, 14);
   1 := INDEX MAX 3;
   null := INDEX MAXIMUM ();
   null := INDEX MAXIMUM (1, "abc");
```

9.12.22.5 *Absence of Other Index Operators*

There are no index extraction equivalents for last and first as **index first** would always return 1 and **index last** is equivalent to the count operator.

9.13 Query Aggregation Operators

9.13.1 General Properties

The query aggregation operators do not follow the default list handling, or the default primary time handling. They perform aggregation on a list. That is, they take a list as one argument and return a single item as a result. If the list argument is a single item, then it is treated as a list of length one. Unless

otherwise specified, if all the elements of the list have the same primary time, the result maintains that primary time (otherwise the primary time lost).

The unary query aggregation operators (that is, those that do not include the **from** word) may optionally be followed by **of**.

The query aggregation operators follow the default time-of-day handling, when used with a time-of-day argument. The time-of-day value is a point in time within the current day.

9.13.2   Nearest ... From (binary, right-associative)

The **nearest ... from** operator expects a time as its first argument and a list as its second argument. It selects the item from the list whose time of occurrence is nearest the specified time. If any of the elements do not have primary times, the result is **null** (the argument can always be qualified by **where time of it is present**, if this is not desired behavior). In the case of a tie, the element with the smallest index is used. The primary times of the argument are maintained. Assume that **data** is a list that is the result of a query with these values: **12, 13, 14**; **data** has these primary times:1990-03-15T15:00:00, 1990-03-16T15:00:00, 1990-03-17T15:00:00; and now is 1990-03-18T16:00:00. The usage of the **nearest ... from** operator is:

```
<n:any-type> := NEAREST <1:times> FROM <m:any-type>
   13 := NEAREST (2 days ago) FROM data;
   null := NEAREST (2 days ago) FROM (3, 4);
   null := NEAREST (2 days ago) FROM ();

   14 := NEAREST 12:00 FROM data;
   // the same as NEAREST 1990-03-18T12:00:00

   14 := NEAREST 23:00 FROM data;
   // the same as NEAREST 1990-03-18T23:00:00
```

A more detailed example: a blood glucose query result contains following values **7.0, 10.0, 12.0, query_result** has the primary times 1990-03-18T12:00:00, 1990-03-18T12:30:00, 1990-03-18T13:00:00, and now is 1990-03-18T16:00:00.

The blood glucose level before lunch can be retrieved with:

```
   7.0 := NEAREST 12:00 FROM query_result;
```

The blood glucose level after ½ hour is:

```
   12.0 := NEAREST 12:30 FROM query_result;
```

9.13.3   Index Nearest ... From (binary, right-associative)

The **index nearest ... from** operator functions exactly as the **nearest … from operator** (Section 9.13.2), except that it returns the index of the element rather than the element itself. **Index nearest … from** does not maintain primary time. Assume that **data** is a list that is the result of a query with these values: **12, 13, 14**; **data** has these primary times:1990-03-15T15:00:00, 1990-03-16T15:00:00, 1990-03-17T15:00:00; and now is 1990-03-18T16:00:00. The usage of the **index nearest ... from** operator is:

```
<n:number> := INDEX NEAREST <n:time> FROM <m:any-type>
   2 := INDEX NEAREST (2 days ago) FROM data;
   null := INDEX NEAREST (2 days ago) FROM (3, 4);
```

9.13.4   Index Of … From … (binary, right-associative)

The **index of ... from** operator expects an arbitrary data value as its first argument and a list as its second argument. It returns a list containing the indices of the occurrences of the given data value within the provided list. If there is more than one occurrence all occurrences are returned. The result is **null** if no such value is found in the list or in case of invalid parameters. The primary times of the arguments are not maintained. The usage of the **index of ... from** operator is:

```
<n:number> := INDEX OF <1:any-type> FROM <m:any-type>
   (4) := INDEX OF 4 FROM (1, 2, 3, 4, "5", "six", 7);
   (5) := INDEX OF "5" FROM (1, 2, 3, 4, "5", "six", 7);
  null := INDEX OF 5 FROM (1, 2, 3, 4, "5", "six", 7);

  null := INDEX OF null FROM (1, 2, 3, 4, "5", "six", 7);

  null := INDEX OF 5 FROM null;

   (1) := INDEX OF null FROM null;
   (1) := INDEX OF 5 FROM 5;
(1, 3, 5) := INDEX OF 1 FROM (1, 2, 1, 4, 1, "six", 7);

(3, 5) := INDEX OF null FROM (1, 2, null, 4, null, "six", 7);
```

9.13.5 At Least ... [IsTrue|AreTrue] From … (binary, right-associative)

The **at least ... from** operator expects a number (call it N) as its first argument and a homogeneous list of truth values or Boolean as its second argument. The **at least … from** operator returns the nth largest value of the list of truth values or Boolean. If the first argument is not a number or the second parameter contains a non-truth value or non-Boolean, **null** is returned. If N is greater than the cardinality of the list, **false** is returned. The primary times of the arguments are not maintained. The optional keywords "**IsTrue**" and "**AreTrue**" can be used to increase the readability of statements using the **at least … from** operator. The usage of the operator is:

```
<1:Boolean> := AT LEAST <1:number> [ISTRUE|ARETRUE] FROM <n:Boolean>
   true := AT LEAST 1 IsTrue FROM (TRUE, TRUE, FALSE, FALSE);
   true := AT LEAST 2 AreTrue FROM (TRUE, TRUE, TRUE, FALSE);
   false := AT LEAST 2 FROM (TRUE, FALSE, FALSE, FALSE);
   false := AT LEAST 7 AreTrue FROM (TRUE, FALSE, FALSE);
   null := AT LEAST 2 YEARS FROM (TRUE, FALSE, FALSE);
   null := AT LEAST 2 FROM (TRUE, "true", FALSE);

<1:truth-value> := AT LEAST <1:number> [ISTRUE|ARETRUE] OF <n:truth-value>
   truth value 0.7 := AT LEAST 2 OF (TRUE, truth value 0.7, truth value 0.1,
    FALSE);
   truth value 1 := APPLICABILITY OF (AT LEAST 2 OF (TRUE, truth value 0.7,
    FALSE));
   false := AT LEAST 7 OF (TRUE, truth value 0.1,FALSE);
   null := AT LEAST 2 YEARS OF (TRUE, truth value 0.1,FALSE);
   null := AT LEAST 2 OF (TRUE, "true", truth value 0.1,FALSE);
   truth value 1 := APPLICABILITY OF (AT LEAST 2 OF (TRUE, "true", truth
    value 0.1,FALSE));
```

9.13.6 At Most ... [IsTrue|AreTrue] From … (binary, right-associative)

The **at most ... from** operator expects a number (call it N) as its first argument and a homogeneous list of truth values or Boolean as its second argument. The **at most … from** operator returns the nth smallest value of the list of truth values or Boolean. If the first argument is not a number or the second parameter contains a non-truth value or non-Boolean, **null** is returned. If N is greater than the cardinality of the list, **false** is returned. The primary times of the arguments are not maintained. The optional keywords "**IsTrue**" and "**AreTrue**" can be used to increase the readability of statements using the **at most … from** operator. The usage of the operator is:

```
<1:Boolean> := AT MOST <1:number> [ISTRUE|ARETRUE] FROM <n:Boolean>
   true := AT MOST 2 AreTrue FROM (TRUE, TRUE, FALSE, FALSE);
   false := AT MOST 1 IsTrue FROM (TRUE, TRUE, TRUE, FALSE);
   true := AT MOST 2 FROM (TRUE, FALSE, FALSE, FALSE);
   false := AT MOST 7 FROM (TRUE, FALSE, FALSE);
   null := AT MOST 2 YEARS FROM (TRUE, FALSE, FALSE);
   null := AT MOST 2 FROM (TRUE, "true", FALSE);
```

```
<1:truth-value> := AT MOST <1:number> [ISTRUE|ARETRUE] OF <n:truth-value>
   truth value 0.4 := AT MOST 2 OF (TRUE, truth value 0.4, truth value 0.7,
    FALSE);
   truth value 1 := APPLICABILITY OF (AT MOST 2 OF (TRUE, truth value 0.5,
    truth value 0.7, truth value 0.1, FALSE));
   false := AT MOST 7 OF (TRUE, truth value 0.5, FALSE);
   null := AT MOST 2 YEARS OF (TRUE, 0.5, 0.7, 0.1, FALSE);
   null := AT MOST 2 OF (TRUE, "true", 0.7, 0.1, FALSE);
   truth value 1 := APPLICABILITY OF (AT MOST 2 OF (TRUE, "true", 0.7, 0.1,
    FALSE));
```

9.13.7 Slope (unary, right-associative)

The **slope** operator performs a regression and returns the slope for the result of a query assuming the y axis contains the values and the x axis contains the times. The result is expressed as units per day but is considered to be a number. **Null** results if the argument has fewer than two items. If all the elements of the list have the same primary time, the result is **null**. If one or more of the primary times is non-existent, the result is **null**. The result of the slope operator does not have a primary time. Its usage is (assuming the same **data** as above):

```
<1:number> := SLOPE <n:number>
   1 := SLOPE data;
   null := SLOPE (3, 4);
```

9.14 Transformation Operators

9.14.1 General Properties

The transformation operators do not follow the default list handling, or the default primary time handling. They transform a list, producing another list. If the list argument is a single item, then it is treated as a list of length one. The result is always a list even if there is only one item (except if there is an error, in which case the result is **null**).

Operators that are unary (that is, that do not include the **from** word) may optionally be followed by **of**.

9.14.2 Minimum ... From (binary, right-associative)

The **minimum ... from** operator has one synonym: **min ... from**. It expects a number (call it N) as its first argument and a homogeneous list of an ordered type as its second argument. It returns a list with the N smallest items from the argument list, in the same order that they are in the second argument, and with any duplicates preserved. The result is **null** if N is not a non-negative integer. If there are not enough items in the argument list, then as many as possible are returned. If there is a tie, then it selects the latest of those elements that have a primary time. The primary times of the argument are maintained. Its usage is:

```
<n:ordered> := MINIMUM <1:number> FROM <m:ordered>
   (11, 12) := MINIMUM 2 FROM (11, 14, 13, 12);
   (3) := MINIMUM 2 FROM 3;
   null := MINIMUM 2 FROM (3, "asdf");
   () := MINIMUM 2 FROM ();
   () := MINIMUM 0 FROM (2, 3);
   (1, 2, 2) := MINIMUM 3 FROM (3, 5, 1, 2, 4, 2);
```

The **minimum … from** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the minimum. For example:

```
<n:object> := minimum 2 from <n:object> using it.age; //will return the two
         // youngest persons from a list of persons (represented by objects)
```

9.14.3 Maximum ... From (binary, right-associative)

The **maximum ... from** operator has one synonym: **max ... from**. It expects a number (call it N) as its first argument and a homogeneous list of an ordered type as its second argument. It returns a list with the N

---

largest items from the argument list, in the same order that they are in the second argument, and with any duplicates preserved. The result is **null** if N is not a non-negative integer. If there are not enough items in the argument list, then as many as possible are returned. If there is a tie, then it selects the latest of those elements that have a primary time. The primary times of the argument are maintained. Its usage is:

```
<n:ordered> := MAXIMUM <1:number> FROM <m:ordered>
    (14, 13) := MAXIMUM 2 FROM (11, 14, 13, 12);
    (3) := MAXIMUM 2 FROM 3;
    null := MAXIMUM 2 FROM (3, "asdf");
    () := MAXIMUM 2 FROM ();
    () := MAXIMUM 0 FROM (1, 2, 3);
    (5, 4, 4) := MAXIMUM 3 FROM (1, 5, 2, 4, 1, 4);
```

The **maximum … from** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the maximum. For example:

```
<n:object> := maximum 2 from <n:object> using it.age; //will return the two
            // oldest persons from a list of persons (represented by objects)
```

9.14.4 First ... From (binary, right-associative)

The **first ... from** operator expects a number (call it N) as its first argument and a list as its second argument. It returns a list with the first N items from the argument list. The result is **null** if N is not a non-negative integer. If the list is the result of a time-sorted query, then the returned items are the earliest in time. If there are not enough items in the argument list, then as many as possible are returned. This means that **first 1 from x** differs from **first x** if **x** is empty; the former returns **()** and the latter returns **null**. The primary times of the argument are maintained. Its usage is:

```
<n:any-type> := FIRST <1:number> FROM <m:any-type>
    (11, 14) := FIRST 2 FROM (11, 14, 13, 12);
    (3) := FIRST 2 FROM 3;
    (null, 1) := FIRST 2 FROM (null, 1, 2, null);
    () := FIRST 2 FROM ();
```

9.14.5 Last ... From (binary, right-associative)

The **last ... from** operator expects a number (call it N) as its first argument and a list as its second argument. It returns a list with the last N items from the argument list. The result is **null** if N is not a non-negative integer. If the list is the result of a time-sorted query, then the returned items are the latest in time. If there are not enough items in the argument list, then as many as possible are returned. This means that **last 1 from x** differs from **last x** if **x** is empty; the former returns **()** and the latter returns **null**. The primary times of the argument are maintained. Its usage is:

```
<n:any-type> := LAST <1:number> FROM <m:any-type>
    (13, 12) := LAST 2 FROM (11, 14, 13, 12);
    (3) := LAST 2 FROM 3;
    (2, null) := LAST 2 FROM (null, 1, 2, null);
    () := LAST 2 FROM ();
```

9.14.6 Sublist …Elements [Starting at …] From … (ternary, right-associative)

The **sublist … elements [starting at …] from** operator returns a sublist of elements from a designated target list and is similar to the **substring** operator (see 9.8.10). This sublist consists of the specified number of elements from the source list beginning with the starting position (either the first elements of the list or the specified location within the list). For example **sublist 3 elements starting at 2 from ("E", "x", "a", "m", "p", "l", "e")** would **return ("x", "a", "m")**–a 3 element list beginning with the second element in the source list.

The target list must be a list data type, the starting location within the list must be a positive integer, and the number of elements to be returned must be an integer, or the operator returns **null**. If target is not a list data type, a list with one element is assumed. If a starting position is specified, its value must be an integer between 1 and the length of the list, otherwise an empty list is returned. If the requested number of

elements is greater than the length of the list, the entire list is returned. If a starting point is specified, and the requested number of elements is greater than the size of the list minus the starting point, the resulting list is the original list to the right of and including the starting position. If the number of elements requested is positive the elements are counted from left to right. If the number of elements requested is negative, the elements are counted from right to left. The elements in a sublist are always returned in the order that they appear in the original list. Default list handling is observed. Primary times are preserved.

```
<n:any-type> := SUBLIST <1:number> ELEMENTS [STARTING AT <1:number>] FROM
  <m:any-type>
(1, 2) := SUBLIST 2 ELEMENTS FROM (1, 2, 3, 4, 5);
(1, 2, 3, 4, 5) := SUBLIST 100 ELEMENTS FROM (1, 2, 3, 4, 5);
(4, 5, 6) := SUBLIST 3 ELEMENTS STARTING AT 4 FROM (1, 2, 3, 4, 5, 6, 7);
(4, 5, 6, 7) := SUBLIST 20 ELEMENTS STARTING AT 4 FROM (1, 2, 3, 4, 5, 6,
 7);
null := SUBLIST 2.3 ELEMENTS FROM (1, 2, 3, 4, 5, 6, 7);
null := SUBLIST 2 ELEMENTS STARTING AT 4.7 FROM (1, 2, 3, 4, 5, 6, 7);
null := SUBLIST 3 ELEMENTS STARTING AT "c" FROM (1, 2, 3, 4, 5, 6, 7);
null := SUBLIST "b" ELEMENTS STARTING AT 4 FROM (1, 2, 3, 4, 5, 6, 7);
() := SUBLIST 3 ELEMENTS STARTING AT 4 FROM 281471;
(4) := SUBLIST 1 ELEMENTS STARTING AT 4 FROM (1, 2, 3, 4, 5, 6, 7);
(4) := SUBLIST -1 ELEMENTS STARTING AT 4 FROM (1, 2, 3, 4, 5, 6, 7);
(2, 3, 4) := SUBLIST -3 ELEMENTS STARTING AT 4 FROM (1, 2, 3, 4, 5, 6, 7);
(1) := SUBLIST 1 ELEMENTS FROM (1, 2, 3, 4, 5, 6, 7);
```

9.14.7 Increase (unary, right-associative)

The **increase** operator returns a list of the differences between successive items in a homogeneous numeric, time, or duration list. There is one fewer item in the result than in the argument; if the argument is an empty list, then **null** is returned. The primary time of the second item in each successive pair is kept. Its usage is:

```
<n:number> := INCREASE <m:number>
(4, -2, -1) := INCREASE (11, 15, 13, 12);
() := INCREASE 3;
null := INCREASE ();
<n:duration> := INCREASE <m:times>
(1 day) := INCREASE (1990-03-01, 1990-03-02);
(1 hour) := INCREASE (13:00:00, 14:00:00);
<n:duration> := INCREASE <m:duration>
(1 day) := INCREASE (1 day, 2 days);
```

9.14.8 Decrease (unary, right-associative)

The **decrease** operator returns a list of the negative differences between successive items in a homogeneous numeric, time, or duration list. There is one fewer item in the result than in the argument; if the argument is an empty list, then **null** is returned. **Decrease** is the additive inverse of **increase**. The primary time of the second item in each successive pair is kept. Its usage is:

```
<n:number> := DECREASE <m:number>
(-4, 2, 1) := DECREASE (11, 15, 13, 12);
() := DECREASE 3;
null := DECREASE ();
<n:duration> := DECREASE <m:times>
((-1) day) := DECREASE (1990-03-01, 1990-03-02);
((-1) hour) := DECREASE (13:00:00, 14:00:00);
<n:duration> := DECREASE <m:duration>
((-1) day) := DECREASE (1 day, 2 days);
```

9.14.9 % Increase (unary, right-associative)

The **% increase** operator has one synonym: **percent increase**. It returns a list of the percent increase between items in successive pairs in a homogeneous number or duration list (the denominator is the first

---

item in each pair; if it is zero, then **null** is returned). The primary time of the second item in each successive pair is kept. Its usage is:

```
<n:number> := % INCREASE <m:number>
    (36.3636, -13.3333) := % INCREASE (11, 15, 13);
    () := % INCREASE 3;
    null := % INCREASE ();
<n:number> := % INCREASE <m:duration>
    (100) := % INCREASE (1 day, 2 days);
```

9.14.10 % Decrease (unary, right-associative)

The **% decrease** operator has one synonym: **percent decrease**. It returns a list of the percent decrease between items in successive pairs in a homogeneous number or duration list (the denominator is the first item in each pair, if it is zero, then **null** is returned). The primary time of the second item in each successive pair is kept. Its usage is:

```
<n:number> := % DECREASE <m:number>
    (-36.3636, 13.3333) := % DECREASE (11, 15, 13);
    () := % DECREASE 3;
    null := % DECREASE ();
<n:number> := % DECREASE <m:duration>
    (-100) := % DECREASE (1 day, 2 days);
```

9.14.11 Earliest ... From (binary, right-associative)

The **earliest ... from** operator expects a number (call it N) as its first argument and a list as its second argument. It returns a list with the earliest N items from the argument list, in the order they appear in the argument list. The result is **null** if N is not a non-negative integer. If any of the elements do not have primary times, the result is **null** (the argument can always be qualified by **where time of it is present**, if this is not desired behavior). If there are not enough items in the argument list, then as many as possible are returned. This means that **earliest 1 from x** differs from **earliest x** if **x** is empty; the former returns **()** and the latter returns **null**. The primary times of the argument are maintained. Its usage is:

```
<n:any-type> := EARLIEST <1:number> FROM <m:any-type>
    () := EARLIEST 2 FROM ();
```

The **earliest … from** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the earliest value. For example:

```
<n:object> := earliest 2 from <n:object> using it.birthday; //will return the
        // two oldest persons from a list of persons (represented by objects)
```

9.14.12 Latest ... From (binary, right-associative)

The **latest ... from** operator expects a number (call it N) as its first argument and a list as its second argument. It returns a list with the latest N items from the argument list, in the order they appear in the argument list. The result is **null** if N is not a non-negative integer. If any of the elements do not have primary times, the result is **null** (the argument can always be qualified by **where time of it is present**, if this is not desired behavior). If there are not enough items in the argument list, then as many as possible are returned. This means that **latest 1 from x** differs from **latest x** if **x** is empty; the former returns **()** and the latter returns **null**. The primary times of the argument are maintained. Its usage is:

```
<n:any-type> := LATEST <1:number> FROM <m:any-type>
    () := LATEST 2 FROM ();
```

The **latest … from** operator can also be extended by the using modifier as defined for the sort operator (see 9.2.4) to allow more complex calculations of the latest value. For example:

```
<n:object> := latest 2 from <n:object> using it.birthday; //will return the
        // two youngest persons from a list of persons (represented by objects)
```

9.14.13 Index Extraction Transformation Operators

These operators behave similarly to their non-index extracting counterparts with the exception that they return the value of the index of the element that matches the specified criteria rather than the element itself. These operators do not maintain primary times.

9.14.13.1 *Index Minimum ... From (binary, right-associative)*

The **index minimum ... from** operator has one synonym: **index min ... from**. It expects a number (call it N) as its first argument and a homogeneous list of an ordered type as its second argument. It returns a list with the indices of the N smallest items from the argument list, in the same order that they are in the second argument, and with any duplicates preserved. The result is **null** if N is not a non-negative integer. If there are not enough items in the argument list, then as many indices as possible are returned. If there is a tie, then it selects the latest of those elements that have a primary time. The primary times of the argument are not maintained. Its usage is:

```
<n:number> := INDEX MINIMUM <1:number> FROM <m:ordered>
    (1, 4) := INDEX MINIMUM 2 FROM (11, 14, 13, 12);
    (3, 4, 6) := INDEX MINIMUM 3 FROM (3, 5, 1, 2, 4, 2);
    null := INDEX MIN 2 FROM (3, "asdf");
    (1) := INDEX MINIMUM 2 FROM 3;
    () := INDEX MINIMUM 0 FROM (2,3);
```

9.14.13.2 *Index Maximum ... From (binary, right-associative)*

The **index maximum ... from** operator has one synonym: **index max ... from**. It expects a number (call it N) as its first argument and a homogeneous list of an ordered type as its second argument. It returns a list with the indices of the N largest items from the argument list, in the same order that they are in the second argument, and with any duplicates preserved. The result is **null** if N is not a non-negative integer. If there are not enough items in the argument list, then as many indices as possible are returned. If there is a tie, then it selects the latest of those elements that have a primary time. The primary times of the argument are not maintained. Its usage is:

```
<n:number> := INDEX MAXIMUM <1:number> FROM <m:ordered>
    (2, 3) := INDEX MAXIMUM 2 FROM (11, 14, 13, 12);
    (2, 3, 5) := INDEX MAXIMUM 3 FROM (3, 5, 1, 2, 4, 2);
    null := INDEX MAX 2 FROM (3, "asdf");
    (1) := INDEX MAXIMUM 2 FROM 3;
    () := INDEX MAXIMUM 0 FROM (2, 3);
```

9.14.13.3 *First… From; Last… From*

There are no index extraction operator parallels for **first … from** and **last … from** as these can be generated using either the **seqto** operator (for **first … from**) or the seqto and **count** operators (for **last … from**). Thus if these functions are needed, use the following:

Index First x From y : 1 seqto x

Index Last x From y : (count(y)-x) seqto count(y)

9.15 Query Transformation Operator

9.15.1 General Properties

The query transformation operator does not follow the default list handling, or the default primary time handling. It transforms a list, producing another list. If the list argument is a single item, then it is treated as a list of length one. The result is always a list even if there is only one item (except if there is an error, in which case the result is **null**).

The query transformation operator can only be applied to the result of a query, since it requires that a time be associated with each item in the argument list. **Null** is returned if it is used on other data.

The query transformation operator may optionally be followed by **of**.

9.15.2 Interval (unary, right-associative)

The **interval** operator returns the difference between the primary times of succeeding items in a list. It is analogous to **increase**. The primary times of the argument are lost. Its usage is (assuming that **data** is the result of a query with these primary times: **1990-03-15T15:00:00, 1990-03-16T15:00:00, 1990-03-18T21:00:00**):

```
<n:duration> := INTERVAL <m:any-type>
   (1 day, 2.25 days) := INTERVAL data;
   null := INTERVAL (3, 4);
```

9.16 Numeric Function Operators

The numeric function operators are all unary functions that work with numbers. When an illegal operation is attempted (for example, **log 0**) then **null** is returned.

9.16.1 Arccos (unary, right-associative)

The **arccos** operator calculates the arc-cosine (expressed in radians) of its argument. Its usage is:

```
<n:number> := ARCCOS <n:number>
   0 := ARCCOS 1;
```

9.16.2 Arcsin (unary, right-associative)

The **arcsin** operator calculates the arc-sine (expressed in radians) of its argument. Its usage is:

```
<n:number> := ARCSIN <n:number>
   0 := ARCSIN 0;
```

9.16.3 Arctan (unary, right-associative)

The **arctan** operator calculates the arc-tangent (expressed in radians) of its argument. Its usage is:

```
<n:number> := ARCTAN <n:number>
   0 := ARCTAN 0;
```

9.16.4 Cosine (unary, right-associative)

The **cosine** operator has one synonym: **cos**. It calculates the cosine of its argument (expressed in radians). Its usage is:

```
<n:number> := COSINE <n:number>
   1 := COSINE 0;
```

9.16.5 Sine (unary, right-associative)

The **sine** operator has one synonym: **sin**. It calculates the sine of its argument (expressed in radians). Its usage is:

```
<n:number> := SINE <n:number>
   0 := SINE 0;
```

9.16.6 Tangent (unary, right-associative)

The **tangent** operator has one synonym: **tan**. It calculates the tangent of its argument (expressed in radians). Its usage is:

```
<n:number> := TANGENT <n:number>
   0 := TANGENT 0;
```

9.16.7 Exp (unary, right-associative)

The **exp** operator raises mathematical e to the power of its argument. Its usage is:

```
<n:number> := EXP <n:number>
```

```
                          1 := EXP 0;
```

9.16.8 Log (unary, right-associative)

The **log** operator returns the natural logarithm of its argument. Its usage is:

```
         <n:number> := LOG <n:number>
            0 := LOG 1;
```

9.16.9 Log10 (unary, right-associative)

The **log10** operator returns the base 10 logarithm of its argument. Its usage is:

```
         <n:number> := LOG10 <n:number>
            1 := LOG10 10;
```

9.16.10 Int (unary, right-associative)

The **int** operator returns the largest integer less than or equal to its argument (truncates towards negative infinity). It is synonymous with **floor** (Section 9.16.11). Its usage is:

```
         <n:number> := INT <n:number>
           -2 := INT (-1.5);
           -2 := INT (-2.0);
            1 := INT (1.5);
           -3 := INT (-2.5);
           -4 := INT (-3.1);
           -4 := INT (-4);
```

9.16.11 Floor (unary, right-associative)

The **floor** operator is synonymous with **int**. It returns the largest integer less than or equal to its argument (truncates towards negative infinity).

9.16.12 Ceiling (unary, right-associative)

The **ceiling** operator returns the smallest integer greater than or equal to its argument (truncates towards positive infinity). Its usage is:

```
         <n:number> := CEILING <n:number>
           -1 := CEILING (-1.5);
           -1 := CEILING (-1.0);
            2 := CEILING 1.5;
           -2 := CEILING (-2.5);
           -3 := CEILING (-3.9);
```

9.16.13 Truncate (unary, right-associative)

The **truncate** operator removes any fractional part of a number (truncates towards zero). Its usage is:

```
         <n:number> := TRUNCATE <n:number>
           -1 := TRUNCATE (-1.5);
           -1 := TRUNCATE (-1.0);
            1 := TRUNCATE 1.5;
```

9.16.14 Round (unary, right-associative)

The **round** operator rounds a number to an integer.

For positive numbers: If the fractional portion of the operand is greater than or equal to 0.5, the operator rounds to the next highest integer. Fractional portions less than 0.5 round to the next lowest integer.

For negative numbers: If the absolute value of the fractional portion of the operand is greater than or equal 0.5, the operator rounds to the next lower negative integer. Fractional portions with absolute values less than 0.5 round to the next highest integer.

Its usage is:

```
<n:number> := ROUND <n:number>
    1 := ROUND 0.5;
    3 := ROUND 3.4;
    4 := ROUND 3.5;
   -4 := ROUND (-3.5);
   -3 := ROUND (-3.4);
   -4 := ROUND (-3.7);
```

9.16.15 Abs (unary, right-associative)

The **abs** operator returns absolute value of its argument. Its usage is:

```
<n:number> := ABS <n:number>
    1.5 := ABS (-1.5);
```

9.16.16 Sqrt (unary, right-associative)

The **sqrt** operator returns the square root of its argument. Because imaginary numbers are not supported, the square root of a negative number results in **null**. Its usage is:

```
<n:number> := SQRT <n:number>
    2 := SQRT 4;
    null := SQRT(-1);
```

9.17 Time Function Operator

The time function operator does not follow the default primary time handling.

9.17.1 Time (unary, right-associative)

The **time** operator returns the primary time (that is, time of occurrence) of the result of a value derived from a query (see Section 8.9). **Null** is returned if it is used on data that has no primary time. The result of **time** preserves the primary time of its argument; so **time time x** is equivalent to **time x**. Its usage is (assuming that **data0** is the result of a query with one element whose primary time is: **1990-03-15T15:00:00**):

```
<n:time> := TIME [OF] <n:any-type>
    1990-03-15T15:00:00 := TIME OF data0;
    1990-03-15T15:00:00 := TIME TIME data0;
    (null, null) := TIME (3, 4);
```

The inverse of the **time** operator (to set the primary time of a value) can be achieved by using **time** on the left side of an assignment statement. For example:

```
TIME [OF] <n:any-type> := <n:time>
    TIME data1 := time data2;
```

If the identifier on the left hand side of an assignment statement refers to a list, the behavior of the time assignment is undefined. Future versions of the Arden Syntax standard may formally define this behavior. If the right side of the assignment statement does not refer to a time value, the **time** operator assigns **null** to the primary time of the identifier at the left hand side.

9.17.2 Time of Objects

When an object is passed to the **time** operator, the result will be null if one or more attributes do not reference a data item with a primary time, if the data contain primary times but those times differ, or if the object contains no attributes. If all the objects attributes refer to data items with primary times, and all those

times are equivalent, then this time is returned as the time of the object. If an attribute contains a list, then the primary time of the object is not defined (returns null) since lists do not have a specific primary time.

```
LabResult := OBJECT [id, value];
result := new LabResult;

result.id := 123;
time of result.id := 2004-01-16T00:00:00;
result.value := 1.0;
time of result.value := 2004-01-16T00:00:00;

2004-01-16T00:00:00 := time of result; // all attributes have same primary
    time
2004-01-16T00:00:00 := time of result.id;

time of result.id := 2004-01-17T00:00:00;
null := time of result;              // primary times differ
2004-01-17T00:00:00 := time of result.id;
```

9.17.3   Attime (binary, right-associative)

The **attime** operator constructs a time value from two time and time-of-day arguments. The result consists of the date of the time arguments and the time of the time-of-day argument. **Null** is returned if it is used with other arguments than time and time-of-day. The primary times are lost.

```
<n:time> := <n:time> ATTIME <n:time-of-day>
   2006-06-20T15:00:00 := now ATTIME 15:00:00;
   2001-01-01T14:30:00 := TIME OF intuitive_new_millenium ATTIME 14:30:00;
```

This operator was known as the **at** operator in Arden Syntax 2.6. The change from **at** to **attime** was made to resolve a conflict in context-free grammar (Annex 1) and remove the need for precedence rules to properly parse write statements (13.2.1) that utilize destinations.

9.18   Object Operators

9.18.1   Dot (binary, right-associative)

The **dot** operator (".") selects an attribute from an object based on the name following the dot. It takes an expression and an identifier. The expression typically evaluates to an object or a list of objects.

```
<n:any-type> := <expr> "." <identifier>
```

If the expression does not evaluate to an object, or if the object does not contain the named attribute, then null is returned. If the expression evaluates to a list, normal Arden list handling is used, and a list is returned. Therefore, if the expression is a list of objects, then a list (of the same length) of the attribute values named by the identifier is returned (a common usage).

```
NameType := object [FirstName, LastName];
/* Assume namelist contains a list of 2 NameType objects */
("John", "Paul") := namelist.FirstName;
("Lennon", "McCartney") := namelist.LastName;
"John" := namelist[1].FirstName;
 null := namelist[1].Height;
(null, null) := namelist.Height;
```

The dot operator maintains the primary time of the attribute it references.

```
chemistry_panel := object [albumin, calcium, phosphorus];
/* assume patientResult is a single chemistry_panel object with albumin = 4.0
    mg/dL, calcium = 8.7 mg/dL and phosphorus = 3.0 mg/dL on 15 December 2004
    */
calciumPhosphorusProduct := patientResult.calcium * patientResult.phosphorus;
```

```
26.1 := calciumPhosphorusProduct;
2004-12-15T16:00:00 := time of patientResult.calcium;
```

Dot operators may be used together, when objects are stored as attributes of other objects.

```
PatientInfo := object [Name, Birthdate];

/* Assume patient contains an object of type PatientInfo, and the Name
    attribute contains an object of type NameType */
"John" := patient.Name.FirstName;
```

9.18.2 Clone (unary, right-associative)

The **clone** operator returns a copy of its argument. Practically, this only affects objects, because these are the only data types which retain identity across multiple operations. (See Annex A6 for details of object identity). When an object is copied, a new object of the same type is created, and all its fields are initialized by assigning values from corresponding fields in the argument object. The fields, which may contain objects, are themselves cloned, resulting in a deep copy. If any field contains a list, that list is cloned, and any objects stored in the list are also cloned.

The **clone** operator insures that no objects are shared between the argument and the result. The **clone** returns another, distinct object that has the same structure and value as the original object.

Effectively, **clone** works like this depending on the argument type:

Object	A deep copy of the object is returned.
List	A copy of the list is returned, which contains a clone of each item in the original list, in the same order.
Other types	The original item is returned.

```
<n:any-type>  := CLONE [OF] <n:any-type>
<Copy of Object> := CLONE OF <Object>;
   1990-03-15T15:00:00 := CLONE OF 1990-03-15T15:00:00;
   (1, 2, <Copy of Object>) := CLONE (1, 2, <Object>);
   null := CLONE null;
```

When the **clone** operator is applied, the resulting object will contain the same primary times as the argument object. Application of the clone operator to a top-level object or any embedded objects ensures that the fields in any new object have the same primary time as the original fields.

9.18.3 Extract Attribute Names ... (unary, right-associative)

The **extract attribute names** operator expects an object as its argument. It returns a list containing the attribute names of the object argument. Only the immediate attribute names of the argument are returned. If an attribute is itself an object, the attribute names of the embedded object are not returned, i.e. no nested lists. If the argument is not an object, **null** is returned.

```
<n:string> := EXTRACT ATTRIBUTE NAMES <1:any-type>

(in data slot)
MedicationDose := OBJECT [Medication, Dose, Status];
dose := NEW MedicationDose with "Ampicillin", "500mg", "Active";

(in data slot or logic slot)
dose_attributes := extract attribute names dose;
dose_attributes = ("Medication", "Dose", "Status");
```

9.18.4 Attribute … From … (binary, right-associative)

The **attribute … from …** operator expects a string containing the name of an attribute and an object as arguments. It returns the value of the named attribute. If the named attribute is itself an object, the sub-object is returned. If no attributes with the supplied name exists within the named object, null is returned. This is analogous to referring to attributes using dot notation. However, the **attribute … from …** operator allows the name of the attribute to be supplied at run-time rather than requiring knowing the attribute name at design-time.

```
<n:any-type> := attribute <m:string> FROM <m:object>

  (in data slot)
  MedicationDose := OBJECT [Medication, Dose, Status];
  dose := NEW MedicationDose with "Ampicillin", "500mg", "Active";

  (in data slot or logic slot)
  medication_name := attribute "Medication" from dose;
  medication_name = "Ampicillin";

  medication_name := dose.Medication;
  medication_name = "Ampicillin";

  dose_attributes := extract attribute names dose;
  medication_name := attribute dose_attributes[1] from dose;
  medication_name = "Ampicillin";
```

9.19 Fuzzy Operators

9.19.1 Fuzzy Set … (unary, right-associative)

The **fuzzy set …** operator creates a new fuzzy set as described in 8.14.1, 8.14.2, or 8.14.3, according to the provided parameters. The operator returns null if the data types are not compatible. Its usage is:

```
<1:fuzzy-number> := FUZZY SET "(" <1:number>, <1:truth-value>")", "("
   <1:number>, <1:truth-value>")", ...
   Var1 := fuzzy set (2, truth value 0), (3, truth value 1), (4, truth value
   1), (5, truth value 0);

<1:fuzzy-time> := FUZZY SET "(" <1:time>, <1:truth-value>")", "(" <1:time>,
   <1:truth-value>")", ...
   Var2 := fuzzy set (now - 2 days, truth value 0), (now, truth value 1),
   (now + 1 day, truth value 0);
   Var3 := fuzzy set (2001-12-12, truth value 0), (2003-12-12, truth value
   1), (2009-01-01, truth value 0);

<1:fuzzy-duration> := FUZZY SET "(" <1:duration>, <1:truth-value>")", "("
   <1:duration>, <1:truth-value>")", ...
   Var4 := fuzzy set (2 days, truth value 0), (3 days, truth value 1), (4
   days, truth value 1), (5 days, truth value 0);
```

9.19.2 Fuzzified By (binary, non-associative)

The **… fuzzified by …** operator creates a new triangular fuzzy set as described in 8.14.1, 8.14.2, or 8.14.3, according to the provided parameters. The operator returns **null** if the data types are not compatible. Its usage is:

```
<1:fuzzy-number> := <1:number> FUZZIFIED BY <1:number>
```

```
Var1 := 7 fuzzified by 2;

<1:fuzzy-time> := <1:time> FUZZIFIED BY <1:duration>
    Var2 := now fuzzified by 2 days;

<1:fuzzy-duration> := <1:duration> FUZZIFIED BY <1:duration>
    Var3 := 7 days fuzzified by 2 hours;
```

9.19.3 Defuzzified … (unary, right-associative)

The **defuzzified** operator expects a fuzzy data type value as its argument. The operator converts a fuzzy set into a crisp data type. To calculate the result, the **mean of maximum** method is used. This method calculates the average of those intervals' midpoints, which are mapped to the maximum of the fuzzy set image. The usage of the operator is:

```
<n:crisp-type> := DEFUZZIFIED <n:fuzzy-type>
    7 := Defuzzified 7 fuzzified by 2;
```

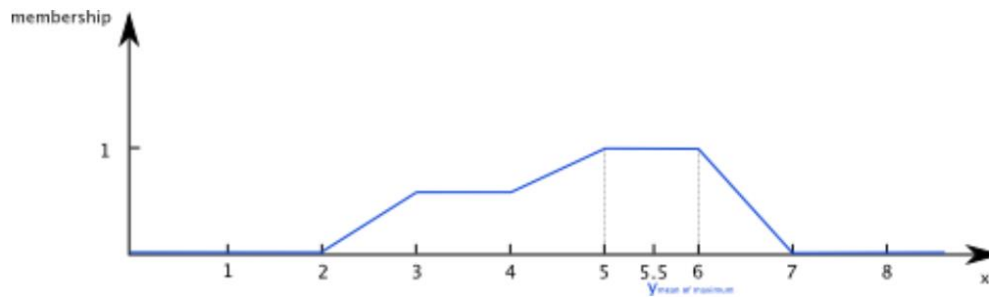

9.19.4 Applicability [of] … (unary, non-associative)

The **applicability of** operator returns the degree of applicability of a value. Since **null** is not allowed as degree of applicability, a value is always returned (default degree of applicability is 1). The result of the **applicability** operator preserves the primary time and the degree of applicability of its argument; therefore, **applicability applicability x** is equivalent to **applicability x**. Its usage is (assuming that data0 has the degree of applicability of 0.44):

```
<n:truth-value> := APPLICABILITY [OF] <n:any-type>
    truth value 0.44 := APPLICABILITY OF data0;
    truth value 0.44 := APPLICABILITY APPLICABILITY data0;
    (truth value 1, truth value 1) := APPLICABILITY (3, 4);
```

The inverse of the **applicability** operator (to set the degree of applicability of a value) can be achieved by using the **applicability** operator on the left side of an assignment statement. For example:

```
APPLICABILITY [OF] <n:any-type> := <n:truth-value>
    APPLICABILITY data1 := TRUTH VALUE 0.44;
```

If the identifier on the left hand side of an assignment statement refers to a list, the behavior of the **applicability** assignment is undefined.

9.19.5 Applicability of Objects

When an object is passed to the **applicability** operator, the result will be null if the attributes are referring to data items with different applicabilities, or if the object contains no attributes. If all the objects attributes refer to data items with equivalent applicability, then this applicability is returned as the applicability of the object. If an attribute contains a list, then the applicability of the object is not defined (returns null) since lists do not have a specific applicability.

```
LabResult := OBJECT [id, value];
```

```
                    result := new LabResult;

                    result.id := 123;
                    APPLICABILITY of result.id := TRUTH VALUE 0.44;
                    result.value := 1.0;
                    APPLICABILITY of result.value := TRUTH VALUE 0.44;

                    truth value 0.44 := APPLICABILITY of result; // all attributes have same
                        applicability
                    truth value 0.44 := APPLICABILITY of result.id;

                    APPLICABILITY of result.id := TRUTH VALUE 0.5;
                    null := APPLICABILITY of result;              // applicabilities differ
                    truth value 0.5 := APPLICABILITY of result.id;
```

9.20 Type Conversion Operator

9.20.1 As Number (unary, non-associative)

The **as number** operator attempts to convert a string or Boolean into a number. If conversion into a number is possible, the number is returned, otherwise **null** is returned. The primary time of the argument is preserved. The regular use of this operator would be the conversion of a string that contains a valid number representation i.e. "123" into the represented number. If the string does not contain a valid number, the result will be **null**. Boolean values are translated as follows: Boolean **true** is represented at 1 and Boolean **false** is represented at 0.

```
            <n:number> := <n:numeric string> AS NUMBER
                5 := "5" AS NUMBER;
                null := "xyz" AS NUMBER;

            <n:number> := <n:Boolean> AS NUMBER
                1 := True AS NUMBER;
                0 := False AS NUMBER;

            <n:number> := <n:number> AS NUMBER

                6 := 6 AS NUMBER;
                (7, 8, 230, 4100, null, null, 1, 0, null, null, null) := ("7", 8,
                "2.3E+2", 4.1E+3, "ABC", Null, True, False, 1997-10-31T00:00:00, now, 3
                days) AS NUMBER;
                ():= () AS NUMBER;
```

9.20.2 As Time (unary, non-associative)

The **as time** operator attempts to convert a given string into a time. If conversion into a time is possible, the time is returned, otherwise null is returned. The primary time of the argument is preserved. The common use of this operator is the conversion of a string containing a valid date/time format as described in ISO 8601:1988(E), e.g., "1999-12-12" or "1999-12-12T13:41", into a time.

```
            <n:time> := <n:string> AS TIME
            <n:time> := <n:time> AS TIME
                1999-12-12 := "1999-12-12" AS TIME;
                null := "xyz" AS TIME;
                (1999-12-12, 1999-12-12, null, null, null, 1997-10-31T00:00:00, null) :=
                ("1999-12-12", 1999-12-12, "ABC", Null, True, "1997-10-31T00:00:00", 3
                days) AS TIME;
                ():= () AS TIME;
```

9.20.3 As String (unary, non-associative)

The **as string** operator attempts to convert any data type into a string. If conversion into a string is possible, the string is returned, otherwise null is returned. The primary time of the argument is preserved.

```
<n:string> := <n:any-type> AS STRING
   "5" := 5 AS STRING;
   "null" := null AS STRING;
   "true" := True AS STRING;
   "false" := False AS STRING;
   ("7", "8", "4100", "ABC", "null", "true", "false", "1997-10-31T00:00:00",
    "3 days") := ("7", 8, 4.1E+3, "ABC", Null, True, False, 1997-10-
    31T00:00:00, 3 days) AS STRING;
   ():= () AS STRING;
```

9.20.4   As Truth Value (unary, non-associative)

The **as truth value** operator attempts to convert a number or Boolean into a truth value. If the conversion into a truth value is possible, the truth value is returned, otherwise null is returned. The primary time of the argument is preserved. The regular use of this operator is to convert a calculated number into the corresponding truth value. If the number is not between 0 and 1, the result will be null. Boolean values are translated as follows: Boolean true is represented as truth value 1 and Boolean false is represented as truth value 0.

```
<n:truth-value> := <n:number> AS TRUTH VALUE
   truth value 0.33 := 0.33 AS TRUTH VALUE;
   null := "xyz" AS TRUTH VALUE;
   null := 400 AS TRUTH VALUE;
<n:truth value> := <n:Boolean> AS TRUTH VALUE
   truth value 1 := True AS TRUTH VALUE;
   truth value 0 := False AS TRUTH VALUE;
   (truth value 0, truth value 1, null, truth value 0.33, null, truth value
    1, truth value 0, null, null, null) := (0, 1, 4.1E+3, 0.33, Null, True,
    False, 1997-10-31T00:00:00, 3 days, "ABC") AS TRUTH VALUE;
   () := () AS TRUTH VALUE;
```

10 LOGIC SLOT

10.1 Purpose

The logic slot uses data about the patient obtained from the data slot, manipulates the data, tests some condition, and decides whether to execute the action slot. It is in this slot that most of the actual health logic is obtained.

10.2 Logic Slot Statements

The logic slot is composed of a set of statements.

10.2.1 Assignment Statement

The assignment statement places the value of an expression into a variable. There are two equivalent versions:

```
<identifier> := <expr>;
LET <identifier> BE <expr>;
```

<identifier> is an identifier; it represents the name of the variable. **<expr>** is a valid expression as defined in Section 7.2.3.

Any reference to the identifier that occurs after the assignment statement will return the value that was assigned from the expression (even if it is in another structured slot; for example, the action slot). A subsequent assignment to the same variable will overwrite the value. If a variable is referred to before its first assignment, **null** is returned. However, it is poor programming practice to depend on this.

The following variables cannot be re-assigned outside of the data slot after they have been assigned in the data slot: **event** (Section 11.2.3), **mlm** (Section 11.2.4), and **interface** (Section 11.2.16). Once defined in the data slot, they should not change.

After executing these statements, the value of variable **var2** is **5**:

```
var1 := 1;
var1 := 3;
var2 := var1 + 2;
```

10.2.1.1 *Object Attribute Assignment*

The identifier on the left side of an assignment statement may be specified by an object attribute reference, using the following form:

<identifier> . <attribute-name>

This allows the assignment to individual attributes of an object. The identifier should name a variable. When the statement is executed, if the variable references an object whose type contains an attribute of the specified name, then that attribute value will be set to the result of evaluating the expression on the right side of the assignment statement.

If at execution time the named variable does not refer to an object, or that object does not contain an attribute of the specified name, then this statement will still evaluate the expression but will not assign the result.

```
Rectangle := Object [Left, Top, Width, Height];
rect := new Rectangle;
// assign attributes
rect.Left := 0;
rect.Top := 0;
rect.Width := 10;
rect.Height := 20;
```

```
// incorrect assignment
rect.Depth := 30;
null := rect.Depth;
```

Note that objects in Arden retain their identity during assignment, references, etc. If more than one reference to an object exists, and that object is modified, other references to the same object will be affected.

```
rect1 := new Rectangle;
// assign attributes
rect1.Left := 0;
rect1.Top := 0;
rect1.Width := 10;
rect1.Height := 20;

rect2 := rect1;        // references the same Rectangle
rect1.Width := 50;

50 := rect2.Width;          // rect2.width reflects change to shared object
```

10.2.1.2 *Enhanced Assignment Statement*

In addition to the basic assignment and simple object assignment statements described above, any expression that ends with a **dot** operation (Section 9.18.1) or **element** operation (Section 9.12.18) may be placed on the left hand side of an assignment statement. This does not apply for multiple-assignment. If the left side contains a parenthesised list of variables, then this arbitrary expression syntax may not be used.

This enhancement streamlines the processing of lists and objects. For example,

```
//simple example using index
my_list := 5, 10, 15;
my_list[3] := 20; //contents of my_list are now 5, 10, 20

//create one object with three nested objects
message_type := OBJECT [id, msg];
my_collection_type := OBJECT [name, message_list];
message_list := ();
for i in 1 seqto 3 do
    message_text := new message_type with i, "this is message " || i;
    message_list := message_list, message_text;
enddo;
my_obj := new my_collection_type with "Reminders", message_list;

//traditional syntax
n := 2;
obj1 := my_obj.message_list[n];
obj1.msg := "this is a replacement message";
message2 := new message_type with 10, "this is message 10";
my_obj.message_list := first (n-1) from my_obj.message_list,
    message2, last (count of my_obj.message_list - n) from
    my_obj.message_list;

var1 := first (n-1) from my_obj.message_list;
var2 := last (count of my_obj.message_list - n) from my_obj.message_list;

//enhanced syntax
n := 2;
my_obj.message_list[n].msg := "this is a replacement message"; //modify nth
    item
my_obj.message_list[n] := new message_type with 10, "this is message 10";
    //replace nth item
```

```
//additional examples
my_obj.message_list.msg := "This is a test"; //modifies message in all
    objects
my_var := my_obj.message_list.msg; //contents of my_var are "This is a test",
    "This is a test", "This is a test"
my_list[1] := my_var; //contents of my_list changed to "This is a test",
    "This is a test", "This is a test", 10, 20
```

10.2.2 If-Then Statement

The **if-then** statement permits conditional execution based upon the value of an expression. It tests whether the expression (**<expr>**) is equal to a single Boolean **true**. If it is, then a block of statements (**<block>**) is executed. (A block of statements is simply a collection of valid statements possibly including other if-then statements; thus the if-then statement is a nested structure.) If the expression results in any truth value (t) between 0 and 1, the block of statements (**<block>**) is executed and the degree of applicability of each variable is multiplied by t. If the result of the expression is a list, or any single item other than **true or a truth value**, the block of statements is not executed. The flow of control then continues with subsequent statements. The if-then statement has several forms:

10.2.2.1 *Simple If-Then Statement*

This form executes **<block1>** if **<expr1>** is **true**:

```
IF <expr1> THEN
   <block>
ENDIF;
```

10.2.2.2 *If-Then-Else Statement*

This form executes **<block1>** if **<expr1>** is **true**; otherwise it executes **<block2>**:

```
IF <expr1> THEN
   <block1>
ELSE
   <block2>
ENDIF;
```

If, however, **<expr1>** is any truth value (t) between 0 and 1, the program splits: **<block1>** and **<block2>** will be executed in parallel. To this end, each branch is provided with its own set of variables which, accordingly, are duplicated.

Moreover, the degree of applicability of each variable is in the case of **<block1>** multiplied by t, in the case of **<block2>** multiplied by $1 - t$. t and $1 - t$ are called **relative weights** of **<block1>** and **<block2>**, respectively. The weight of an MLM evaluation is 1 as long as it does not split.

The program may branch several times. When the weight of the current branch is w and the MLM evaluation enters a branch with relative weight t, the weight will be reduced to w · t.

In a branch of weight **w**, the range of the degree of applicability of any variable is [0, **w**]. Whenever the content of a variable is changed, its degree of applicability will be reduced to **w,** if necessary. For example:

```
Var := 0;
Con := truth value 0.2;
If con then
  Var := Var + 1;
Else
  Var := Var + 3;
Endif;
```

The result of this example are two branches of the MLM execution, where in the first branch Var has the value 1 and the degree of applicability 0.2 and in the second branch Var has the value 3 and the degree of applicability 0.8. That is, the execution of the MLM returns two different values with different degrees of applicability. A nested example would be:

```
Logic:
   Var := 0;
   Bool_true := true;
   Con := truth value 0.2;
   con_second := truth value 0.3;
   IF Con THEN
       Var := Var + 1;
       IF con_second THEN
           Var := Var + 1;
       ELSE
           Var := Var + 3;
       ENDIF;
   ELSE
       Var := Var + 3;
   ENDIF
   CONCLUDE TRUE;
Action:
   WRITE Var;
```

As above, the MLM execution splits into 2 branches on the first IF statement. The second IF statement branches the first branch again into 2 separate executions. Those 3 Branches are executed in parallel.

The expected output:

- 2 with applicability=0.06 (THEN->THEN)

- 4 with applicability=0.14 (THEN->ELSE)

- 3 with applicability=0.8 (ELSE)

The sum of all applicabilities of a variable is 1.

If a conclude statement occurs within a branch the execution of this branch stops immediately. The execution of all other branches continues. For example:

```
Logic:
   Var := 0;
   Bool_true := true;
   Con := truth value 0.2;
   IF Con THEN
       Var := Var + 1;
       CONCLUDE FALSE;
   ELSE
       Var := Var + 3;
   ENDIF;
   CONCLUDE TRUE;
Action:
   WRITE Var;
```

As specified, the CONCLUDE statement stops the execution of the affected branch. The other branch is executed until the end of the MLM and the expected output is 3 with applicability of 0.8.

10.2.2.3   *If-Then-Elseif Statement*

This form sequentially tests each of the expressions **<expr1>** to **<exprN>** (there may be any number of them). When it finds one that is **true**, its associated block is executed. Once one block is executed, no other expressions are tested, and no other blocks are executed. If none of the expressions is true, then **<blockE>** is executed. The **else <blockE>** portion is optional. Its form is:

```
IF <expr1> THEN
   <block1>
ELSEIF <expr2> THEN
   <block2>
```

```
          ELSEIF <expr3> THEN
             <block3>
       ...
       ELSEIF <exprN> THEN
             <blockN>
       ELSE
             <blockE>
       ENDIF;
```

If the expressions are truth values, the execution of the MLM is split into n branches. Branching into n + 1 blocks is possible by the following statement:

```
       IF <expr₁> then <block1>
       ELSEIF <expr₂> then <block2>
       ...
       ELSEIF <exprN> then <blockN>
       ELSE <blockN+1>
       ENDIF;
```

In this case, the relative weight t_i of the ith branch is given by **<expr$_i$>**, where i = 1, ..., n. If **<expr$_i$>** is undefined, it is treated as $t_i = 0$, in which case the branch is not executed. Moreover, if the sum of the t_i is strictly smaller than 1, the relative weight of block$_{n+1}$ will be $1 - t_1 - ... - t_n$, otherwise this block is skipped.

10.2.2.4   *If-Then-Elseif-Aggregate Statement*

As shown in section 10.2.2.2, the program execution is split, if the condition of an if-then-else statement evaluates to any truth value between 0 and 1.

Once all branches of a program have completed their execution in parallel, because of an unsharp condition, it is difficult to give a general recommendation on how the program should proceed. Two possibilities exist:

(A)   The program remains split, that is, all subsequent commands are executed in parallel as well, the action slot included.

(B)   The program reunifies. The multiplied variables are merged into single ones.

Both options are available and (A) is the default. Which possibility is chosen should be decided individually, according to the characteristics of each situation.

If (A) is selected, the MLM's results will be provided by each branch separately. The application to which the results are sent−the host system or the calling MLM−must be prepared to deal with the situation. If the MLM is called by another MLM and returns data, the calling MLM splits accordingly as well.

The possibility (B) implies that the task of combining divergent pieces of information is executed within the MLM itself. To opt for (B), the final line of an if-then-else statement is modified: after the keyword endif, the keyword **aggregate** is added. Thus, when writing

```
       IF <expr> then <block1>
       ELSE <block2>
       ENDIF AGGREGATE;
```

the two branches unify after their execution. The program weight is then set to the sum of the weight of the branches, i.e., to the same value as before.

Moreover, corresponding variables are aggregated.

Let Var be a variable defined in at least one branch. As far as the main component is concerned, the procedure is as follows:

- If the content of Var is the same in each branch, the content is taken over.

- Otherwise, if Var is defined in all branches and of the same simple data type except string, the contents are aggregated according to their **weighted middle**.

- If Var is of the same compound type in all branches, we proceed successively with the components in the same manner.

- In the remaining cases, Var is set to null.

The aggregation of the contents of variables, with respect to the degree of applicability and the primary time, is straightforward. The primary time of Var is transferred if coincident in all branches. If distinct times appear, the primary time will be set to **null**.

Furthermore, as might be expected, the degrees of applicability are added. Thus, if left unchanged during the execution of all branches, the degree of applicability prior to the execution of the if-then-else statement will be restored. For example:

```
Logic:
    Var := 0;
    Bool_true := true;
    Con := truth value 0.2;
    IF Con THEN
        Var := Var + 1;
    ELSE
        Var := Var + 3;
    ENDIF AGGREGATE
    CONCLUDE TRUE;
Action:
    WRITE Var;
```

The MLM execution branches at the IF statement and the expressions in the THEN and ELSE branch are executed in parallel. When execution reaches the ENDIF AGGREGATE statement the aggregated value of Var is calculated. After the ENDIF AGGREGATE statement Var has the value $(0.2*1 + 0.8*3) / (0.2 + 0.8)$ = 2.6. The expected output is 2.6 with the applicability of 1.

Example X2.12 illustrates the difference between using the aggregate and not using aggregate. If the MLM is called with an age of 19.9 years the results will be 8 with applicability of 0.1 and 15 with applicability of 0.9. If the MLM is adjusted to use aggregate at the endif the recommended dose will be 14.3 $(8*0.1+15*0.9)$.

10.2.2.5 *Treatment of Null*

It is important to emphasize that non-**true** is different from **false**. That is, the **else** portion of the **if-then-else** statement is executed whether the expression is **false**, or **null**, or anything other than **true**. Thus these two **if-then** statements, which appear to be the same, produce different results when **var1** is **null**.

```
IF var1 THEN
    var2 := 0;
ELSE
    var2 := 45;
ENDIF;

IF not(var1) THEN
    var2 := 45;
ELSE
    var2 := 0;
ENDIF;
```

To avoid the **null** problem, it is safer to test for existence first, then test for **true**.

```
IF var1 is Boolean THEN
    IF var1 THEN
        var2 := "var1 is true";
    ELSE
        var2 := "var1 is false";
    ENDIF;
ELSE
```

```
                        var2 := "var1 is null or some other type";
                ENDIF;
```

10.2.2.6   *Treatment of Lists*

Lists are always non-true; therefore using an expression that contains a list will always produce the same negative result. Instead, one of the Boolean aggregation operators should be used: **any**, **all**, or **no** (see Sections 9.12.13, 9.12.14, and 9.12.15). For example, to execute a statement if any of the elements in **Bool_list** is true, use:

```
                IF any(Bool_list) THEN
                    var2 := 0;
                ENDIF;
```

10.2.3   Switch-Case Statement

The **switch-case** statement permits conditional execution based on the value of an expression. It tests whether an expression (**<expr1>, <expr2>, <expr3> …**) is equal to the value of the provided variable (**<var>**). If the expression is a fuzzy set the **is [in]** operator is used to test equality, in all other cases the **equals** operator is used. If the equality check does not return **false**, the corresponding block of statements (**<block1>, <block2>, <block3> …**) is executed. A block of statements is simply a collection of valid statements, possibly including other **switch-case** statements; thus the **switch-case** statement is a nested structure. If the expression does not match the value of the provided variable, then the corresponding block of statements is not executed. The flow of control then continues with subsequent statements.

The switch-case statement has several forms:

10.2.3.1   *Simple Switch-Case Statement*

This form executes **<block1>** if the value of **<var>** equals **<expr1>** and **<block2>** if the value is equal to **<expr2>**:

```
                SWITCH <var>
                    CASE <expr1>
                            <block1>
                    CASE <expr2>
                            <block2>
                ENDSWITCH;
```

The following example will set the variable "returnVal" to 7 if the value of the incoming variable "inVal" is equal to 1 and to 9 if the value of the incoming variable "inVal" is equal to 2.

```
                switch inVal
                  case 1
                    returnVal := 7;
                  case 2
                    returnVal := 9;
                endswitch;
```

Equivalent to the **if-then-elseif statement** (see Section 10.2.2.3), the execution of **a switch-case** statement can split the program execution into several program branches which will be executed in parallel. This happens if the comparison between the value of a variable and an **<expr>** evaluates to a truth value between 0 and 1. For example:

```
                age := 16;
                young := FUZZY SET (0, truth value 1), (15, truth value 1), (20, truth value
                    0);
                middle_aged := FUZZY SET (15, truth value 0), (20, truth value 1), (60, truth
                    value 1), (70, truth value 0);
                dose := 0;

                switch age
                    case young
```

```
        dose := 10;
   case middle_aged
        dose := 20;
endswitch;
```

The result of this example are two branches of the MLM execution, where in the first branch `dose` has the value 10 and the degree of applicability 0.8 and in the second branch `dose` has the value 20 and the degree of applicability 0.2. That is, the execution of the MLM returns two different values with different degrees of applicability.

10.2.3.2 *Switch-Case-Default Statement*

This form executes **<block1>** if the value of **<var>** equals **<expr1>** and **<block2>** if the value is equal to **<expr2>**. If none of the both match with the value of **<var>** then the default block **<block3>** is executed:

```
SWITCH <var>
    CASE <expr1>
            <block1>
    CASE <expr2>
            <block2>
    DEFAULT
            <block3>
ENDSWITCH
```

The following example will set the variable "returnVal" to 7 if the value of the incoming variable "inVal" is equal to 1, to 9 if the value of the incoming variable "inVal" is equal to 2 and to 0 otherwise.

```
switch inVal
  case 1
    returnVal := 7;
  case 2
    returnVal := 9;
  default
    returnVal := 0; //error state
endswitch;
```

Equivalent to the **if-then-else statement** (see Section 10.2.2.3), the execution of **a switch-case-default** statement can split the program execution into several program branches which will be executed in parallel. This happens if the comparison between the value of a variable and an **<expr>** evaluates to a truth value between 0 and 1. If the sum of the applicabilities of all branches is less than 1, the default block is executed with applicability 1 minus the sum of the applicabilities of the other branches. For example:

```
age := 16;
young := FUZZY SET (0, truth value 1), (15, truth value 1), (17, truth value
    0);
middle_aged := FUZZY SET (15, truth value 0), (20, truth value 1), (60, truth
    value 1), (70, truth value 0);
dose := 0;

switch age
    case young
        dose := 10;
    case middle_aged
        dose := 20;
    default
        dose := 15;
    endswitch;
```

The result of this example are three branches of the MLM execution, where in the first branch `dose` has the value 10 and the degree of applicability 0.5, in the second branch `dose` has the value 20 and the degree of applicability 0.2 and in the third branch `dose` has the value 15 and the degree of applicability 1- (0.5+0.2) = 0.3. That is, the execution of the MLM returns three different values with different degrees of applicability.

10.2.3.3 *Switch-Case-Aggregate Statement*

The aggregate operator in the switch-case-aggregate or switch-case-default-aggregate statement acts exactly like in the **if-then-elseif-aggregate** statement. For example:

```
age := 16;
young := FUZZY SET (0, truth value 1), (15, truth value 1), (17, truth value
    0);
middle_aged := FUZZY SET (15, truth value 0), (20, truth value 1), (60, truth
    value 1), (70, truth value 0);
dose := 0;

switch age
    case young
        dose := 10;
    case middle_aged
        dose := 20;
    default
        dose := 15;
endswitch aggregate;
```

The MLM execution branches at the SWITCH statement and the expressions in the CASE branches are executed in parallel. When execution reaches the ENDSWITCH AGGREGATE statement the aggregated value of dose is calculated. After the ENDSWITCH AGGREGATE statement dose has the value (0.8*10 + 0.2*20) / (0.8 + 0.2) = 12. The expected output is 12 with the applicability of 1. See Section 10.2.2.4 for more details.

10.2.4 Conclude Statement

The **conclude** statement ends execution in the logic slot. If the expression (**<expr>**) in the conclude statement is a truth value > 0, the applicabilities of all variables are multiplied by this value, and the action slot is executed immediately. Otherwise the whole MLM or the current branch of the MLM terminates immediately. No further execution in the logic slot occurs regardless of the expression. There may be more than one **conclude** statement in the logic slot, but only one will be executed in a single run of the MLM. Its form is:

```
CONCLUDE <expr>;
```

The cautions for the **if-then** statement about **null** and list (in Section 10.2.1.2) also hold for the conclude statement.

If no **conclude** statement is executed, then the logic slot terminates after it executes its last statement, and the action slot is not executed. In effect, the default is **conclude false**.

These are valid **conclude** statements:

```
CONCLUDE false;
CONCLUDE potas > 5.0;
```

Furthermore, the reserved word **conclude** can be used in the action slot to retrieve the **degree of applicability** the action slot is executed with.

```
Applicability_of_action_slot:= conclude;
```

10.2.5 Call Statement

The **call** statement permits nesting of MLMs. Given an MLM filename, the MLM can be called directly with optional parameters and return zero or more results. Given an event definition, all the MLMs that are normally evoked by that event can be called; the called MLMs can be given optional parameters and optionally return results. Given an interface definition, the foreign function can be called directly with optional parameters and return zero or more results. There are two basic forms (the pairs represent equivalent versions):

```
<var> := CALL <name>;
LET <var> BE CALL <name>;

<var> := CALL <name> WITH <expr>;
LET <var> BE CALL <name> WITH <expr>;

(<var>, <var>, …) := CALL <name> WITH <expr>;
LET (<var>, <var>, …) BE CALL <name> WITH <expr>;

<var> := CALL <name> WITH <expr>, …, <expr>;
LET <var> BE CALL <name> WITH <expr>, …, <expr>;

(<var>, <var>, …) := CALL <name> WITH <expr>, …, <expr>;
LET (<var>, <var>, …) BE CALL <name> WITH <expr>, …, <expr>;
```

10.2.5.1 *Commas*

Because arguments to a call are separated by commas (see **argument**, Section 11.2.5), and comma is also an operator (list construction, see Section 9.2.1), there is an apparent ambiguity. This ambiguity is resolved in favor of comma as a parameter separator. Any argument expression containing the comma operator or another operator of the same or lower precedence must be enclosed in parentheses. For example,

This call passes three arguments:

```
x := CALL xxx with (a, b), (c merge d), e + f;
```

This call passes two arguments:

```
y := CALL yyy WITH expr1, expr2;
```

This call appears similar to the one above, but it only passes one argument :

```
z := CALL zzz WITH (expr3, expr4);
```

10.2.5.2 *<name>*

<name> is an identifier that must represent either a valid MLM variable as defined by the MLM statement in the data slot (see Section 11.2.4), a valid event variable as defined by the event statement in the data slot (see Section 11.2.3), a valid interface variable as defined by the interface statement in the data slot (see Section 11.2.16), or an MLM, event, or interface variable defined through the use of an include statement (Section 11.2.20).

10.2.5.3 *<exprs>*

<expr>s are optional parameters, which may be of any type, including list and null. Primary times associated with the parameter are maintained.

10.2.5.4 *<var>*

<var> is an identifier that represents the local variable that will be assigned the result.

10.2.5.5 *MLM Call*

If **<name>** is an MLM variable, then when the **call** statement is executed, the main MLM (that is, the one issuing the call) is interrupted, and the named MLM is called. If the called MLM has **argument** statement(s) in its data slot (see Section 11.2.5), then the values of the **<expr>**s are assigned. If a called MLM's **argument** statement has more variables (parameters) than sent by the call statement, then **null** is assigned to the extra variable(s). If the call statement passes more variables (parameters) than the called MLM is expecting, the additional parameters are silently dropped. The called MLM is executed, and when it terminates, execution of the main MLM resumes. If the called MLM concludes true and there is a return statement in the called MLM's action slot (see Section 13.2.2), then the value of its expression is assigned to **<var>**. If the return statement has more values than the calling MLM can accept, then the extra return values are silently dropped. If the return statement has fewer values than the calling MLM is expecting, then the extra return values are **null**. If there is no return statement, or if the called MLM concludes false, then **null** is assigned to **<var>**. Examples:

```
var1 := CALL my_mlm1 WITH param1, param2;

(var2, var3, var4) := CALL my_mlm2 WITH param1, param2;
```

10.2.5.6 *Event Call*

If **<name>** is an **event** variable, then execution is similar. The main MLM is interrupted, and all the MLMs whose evoke slots refer to the named event are executed (see Section 14). They each receive the parameters if there are any via their argument statement(s). The results of all called MLM's return statements are concatenated together into a list; called MLMs with no return statement and called MLMs that return a single **null** are not included in the result. The order of the returned values is implementation dependent. The result is assigned to **<var>**, and execution continues. **<var>** will always be a list, even if it has one item. Example:

```
var1 := CALL my_event WITH param1, param2;
```

10.2.5.7 *Interface Call*

If **<name>** is an interface variable, then when the **call** statement is executed, the MLM (that is, the one issuing the call) is interrupted, and the named interface is called. If the called interface functions accept variables (parameters), then the values of the **<expr>**s are assigned. If a called interface's function expects more variables (parameters) than sent by the call statement, then **null** is assigned to the extra variable(s). The called function is executed, and when it finishes, execution of the MLM resumes. If the called function returns one or more values, then the values are assigned to the **<var>s**. If the function returns more values than the calling MLM can accept, then the extra return values are silently dropped. If the interface function returns fewer values than the calling MLM is expecting, then the extra values are **null**. If the function does not return any values, then **null** is assigned to **<var>**. Examples:

```
var1 := CALL my_interface_function1 WITH param1, param2;

(var1, var2, var3) := CALL my_interface_function2 WITH param1, param2;
```

10.2.5.8 *Example: Call Statement*

Here is a valid **call** statement:

```
/* Define find_allergies MLM */
find_allergies := MLM 'find_allergies';
/* Lists two medications and their allergens */
med_orders:= ("PEN-G", "aspirin");
med_allergens := ("penicillin", "aspirin");
/* Lists three patient allergies and their reactions */
patient_allergies := ("milk", "codeine", "penicillin");
patient_reactions := ("hives", NULL, "anaphylaxis");
/* Passes 4 arguments and receives 3 lists as values */
(meds, allergens, reactions) := call find_allergies with med_orders,
                        med_allergens,
                        patient_allergies,
                        patient_reactions;
```

10.2.5.9 *Example: Interface Statement*

Here is a valid **interface** statement:

```
/* Define find_allergies external function*/
find_allergies := INTERFACE
    {\\RuleServer\AllergyRules\my_institution\find_allergies.exe};
/* Lists two medications and their allergens */
med_orders := ("PEN-G", "aspirin");
med_allergens := ("penicillin", "aspirin");
/* Lists three patient allergies and their reactions */
patient_allergies := ("milk", "codeine", "penicillin");
patient_reactions := ("hives", NULL, "anaphylaxis");
/* Passes 4 arguments and receives 3 lists as values */
```

```
(meds, allergens, reactions) := call find_allergies with med_orders,
                           med_allergens,
                           patient_allergies,
                           patient_reactions;
```

10.2.5.10 *Enhanced Assignment in Call Statement*

The call statement also supports the same enhanced assignment syntax described in the assignment statement (Section 10.2.1.2)

10.2.6   While Loop

A simple form of looping is provided by the **while** loop. Its form is:

```
WHILE <expr> DO
    <block>
ENDDO;
```

The **while** loop tests whether an expression (**<expr>**) is equal to a single Boolean **true** (similar to the conditional execution introduced in the **if ... then** syntax - see Section 10.2.1.2). If it is, the block of statements (**<block>**) is executed repeatedly until <**expr**> is not **true**. If **<expr>** is not **true**, the block is not executed.

Authors should take care when using **while** loops in MLMs, since it is possible to create infinite loops. It is the author's responsibility, not the compiler, to avoid infinite looping.

Here is an example:

```
/* Initialize variables */
a_list:= ();
m_list:= ();
r_list:= ();
num:= 1;
/* Checks each allergen in the medications to determine if the patient is
    allergic to it */
while num <= (count med_allergen) do
    allergen:= last(first num from med_allergens);
    allergy_found:= (patient_allergies = allergen);
    reaction:= patient_reactions where allergy_found;
    medication:= med_orders where (med_allergens = allergen);
    /* Adds the allergen, medication, and reaction to variables that will */
    /* be returned to the calling MLM */
    If any allergy_found then
       a_list:= a_list, allergen;
       m_list:= m_list, medication;
       r_list:= r_list, reaction;
    endif;
    /* Increments the counter that is used to stop the while-loop */
    num:= num + 1 ;
enddo;
```

10.2.6.1 *Breakloop Statement*

The block of statements (**<block>**) of a while loop may contain a **breakloop** statement. If the execution reaches such a **breakloop** statement, the direct superior loop will be aborted immediately. If the breakloop statement occurs within a nested loop, it will always apply to the innermost loop only. **Breakloop** statements are only allowed inside of loops.

An example is:

```
num:= 1;
/* Checks each allergen in the medications and stops if patient is allergic
    to it */
while num <= (count med_allergen) do
```

```
                    allergen:= last(first num from med_allergens);
                    allergy_found:= (patient_allergies = allergen);
                    /* be returned to the calling MLM */
                    If any allergy_found then
                        breakloop;  // execution of the while-loop will stop immediately
                    endif;
                    /* Increments the counter that is used to stop the while-loop */
                    num:= num + 1 ;
                    [...]
                enddo;
```

10.2.7   For Loop

Another form of looping is provided by the **for** loop. Its form is:

```
            FOR <identifier> in <expr> DO
                <block>
            ENDDO;
```

The **<expr>** will usually be a list generator. If **<expr>** is empty or null, the block is not executed.
Otherwise, the block is executed with the **<identifier>** taking on consecutive elements in **<expr>**. The
<identifier> cannot be assigned to inside the **<block>** (the compiler must produce a compilation error if
this is attempted). After the **enddo**, the **<identifier>** becomes undefined and its value should not be used. A
compiler may flag this as an error.

Here is an example:

```
            /* Initialize variables */
            a_list:= ();
            m_list:= ();
            r_list:= ();
            /* Checks each allergen in the medications to determine if the patient is
                allergic to it */
            for allergen in med_allergens do
                allergy_found:= (patient_allergies = allergen);
                reaction:= patient_reactions where allergy_found;
                medication:= med_orders where (med_allergens = allergen);
                /* Adds the allergen, medication, and reaction to variables that will */
                /* be returned to the calling MLM */
                If any allergy_found then
                    a_list:= a_list, allergen;
                    m_list:= m_list, medication;
                    r_list:= r_list, reaction;
                endif;
            enddo;
```

Here is an example using a set number of iterations:

```
            for i in (1 seqto 10) do
                …
            enddo;
```

10.2.7.1   *Breakloop Statement*

The **breakloop** statement, defined in Section 10.2.6.1, is also permitted in the **<block>** of the for loop.
When a **breakloop** statement is executed, the **<identifier>** becomes undefined and its value should not be
used.

10.2.8   New Statement

The **new** statement causes a new object to be created, and assigns it to the named variable.

```
            <var> := NEW <object-identifier>
            <var> := NEW <object-identifier> WITH <expr 1>, <expr 2>, <expr n>
```

```
            LET <var> BE NEW <object-identifier>
            LET <var> BE NEW <object-identifier> WITH <expr 1>, <expr 2>, <expr n>
```

<object-identifier> is a name which represents an object type declared previously by an **object or linguistic variable** declaration (see Section 11.2.17, 11.2.18).

```
            MedicationDose := OBJECT [Medication, Dose, Status];
            dose := NEW MedicationDose with "Ampicillin", "500mg", "Active";
```

In the simple case (without the **with** clause) all attributes of the object are initialized to null. In the full statement, a set of 1 or more comma-separated expressions should follow the **with** reserved word. Each expression is evaluated and assigned as a value of an attribute of the object. They are assigned in the order the attributes were declared in the **object** statement. If the number of expressions is less than the number of attributes, remaining attributes are initialized to null. If the number of expressions is greater than the number of attributes, the extra expressions are evaluated but the results are silently discarded.

As with a **call** statement, commas between expressions will be considered as separating successive attribute initializer expressions rather than as defining a list. If you want to initialize an attribute with a list you need to enclose the list in parentheses. See Section 10.2.5.1 for detailed information.

```
            dose := NEW MedicationDose with "Ampicillin", ("500", "700"), "Active";
```

10.2.8.1 *New Statement with Named Initializer*

There are times when the MLM author may wish to initialize one or more fields explicitly, not necessarily in the order they are declared. It is desirable to have an easy way to initialize certain fields (attributes) directly by name. Allowing field initialization by name is clearer in the MLM code, especially when the object has a large number of fields.

```
        my_var := NEW <object-type>
            { WITH <expr_1>, <expr_2>, ..., <expr_n> }
            { WITH [ attribute_1 := <expr_1>, attribute_2 := <expr_2>, ...,
              attribute_3 := <expr_3>] }
```

The first WITH clause is optional, and allows one or more Arden expressions to be specified. They will get evaluated in order and initialize attributes of the object beginning with the first field specified in the OBJECT declaration.

The second WITH clause is also optional, and uses the square braces [,] to distinguish itself from the ordered parameters of the first WITH clause. The attribute_1,... should be declared names of object attributes. The attribute names may occur in any order, and allow the MLM author to indicate that one or more attributes should be set following the ordered attribute initialization (the first WITH clause). In many cases this may be clearer and more succinct, such as when you wish to set one of the last fields in the attribute list and allow previous fields to have default (null) values.

Note that although both WITH clauses are optional, if they both occur, the ordered attribute list must precede the named initializer list. The named initializer list will also take precedence in the case that an attribute gets initialized in both the ordered list and the named list.

Example:

```
    obj_def := object [x, y, z];
    testobj := NEW obj_def with [z:=10, y:="roger"];
```

10.3 Logic Slot Usage

The general approach in the logic slot is to use the operators and expressions to manipulate the patient data obtained in the data slot in order to test for some condition in the patient. Once sufficient data, positive or negative, has been amassed the conclude statement is executed. If there is no conclude statement in the logic slot, then it will never conclude **true**, and the action slot will never be executed. Some logic slots are simple (for example, test whether the serum potassium is greater than 5.0), and some are complex (for example, calculate a diagnosis score).

11 DATA SLOT

11.1 Purpose

The purpose of the data slot is to define local variables used in the rest of the MLM. The goal is to isolate institution-specific portions to one slot. Within the data slot, the institution-specific portions are placed in mapping clauses (see Section 7.1.18) so that the institution-specific part does not interfere with the MLM syntax. To simplify maintenance, it is recommended that, in the absence of conditional assignments, **include**, **object**, **mlm**, **interface**, and **event** statements appear before read statements within the data slot.

11.2 Data Slot Statements

The following variables cannot be re-assigned in the logic slot after they have been assigned in the data slot: **event** (Section 11.2.3), **mlm** (Section 11.2.4), **interface** (Section 11.2.16), and **object** (Section 11.2.17). Once defined in the data slot, they should not change.

11.2.1 Read Statement

The main source of data is the patient database. Using the Mapping Clause, each institution can design its own queries based on the local query language; databases may be hierarchical, relational, object-oriented, etc. The vocabulary used to represent entities in the database will vary from institution to institution. (No attempt was made to select a standard vocabulary in this version of this specification.) The **read** statement is designed to isolate those parts of a database query that are specific to an institution from those parts that are universal.

There is no restriction that a **read** statement must derive its input from the patient database. A read statement might access a medical dictionary, for example; or it might interactively request information from somebody (and, if the compiler does on-demand optimization, the interaction might happen only if needed). How this is done is implementation defined.

The database query itself is divided into three parts: the aggregation or transformation operator, the time constraint, and the rest of the query. For backward compatibility, parentheses may be placed around the **<mapping> where <constraint>** part. The general form of the read statement is (there are two equivalent versions):

```
<var> := READ <aggregation> <mapping> WHERE <constraint>;
LET <var> BE READ <aggregation> <mapping> WHERE <constraint>;
```

11.2.1.1 *Definitions*

<var> is a variable that is assigned the result of the query.

<aggregation> is an aggregation operator (see Section 9.12) or a transformation operator (see Section 9.14), which is applied after the query constraints. If **<aggregation>** is omitted, then all the data that satisfy the constraints are returned. Only the following aggregation and transformation operators are permitted:

```
exist
sum
average
avg
minimum
min
maximum
max
last
first
earliest
latest
minimum ... from
min ... from
```

```
max ... from
maximum ... from
last ... from
first ... from
earliest ... from
latest ... from
```

In the default sort ordering, first and last are equivalent to earliest and latest.

<constraint> is any Simple-, Is- or Occur-comparison operator (see Sections 9.4, 9.5, 9.6 and 9.7) with **it** (or **they**) as the left argument, or a combination of those chained with any logical operator (AND, OR, NOT within Section 9.4). In this case **it** refers to the body of the query. The comparison operator specifies the constraint in value, type or time for the query result. If **<constraint>** is omitted, then there are no constraints. Recognising the traditional restriction on occur comparison operators, valid examples for those are:

```
they occurred within the past 3 days
it occurred before the time of surgery
```

A constraint can also be constructed from the classic set of simple and is comparison operators, again with the keyword **it** or **they** to refer to the queries body. Valid examples for those are;

```
it = 3.5
it is not equal "Some Value"
it is within past 3 days
it is not Null
```

Chaining such comparison operators using logical operators allows for complex constraints. As before, the entire constraint must evaluate true if the entry from the query body should be part of the query result:

```
it < 3.5 AND it > 0.0
it is not Null AND it occurred within past 5 days
it > 90 OR it is not 0 AND it occurred within past 10 minutes
```

<mapping> is a valid mapping clause (see Section 7.1.18), which contains the institution-specific part of the query enclosed in curly brackets. It contains any vocabulary terms and any query syntax that is necessary in the institution to perform a query, except that the aggregation and time constraints are missing. **<mapping>** is required.

FHIR queries, to replace the institution specific <mapping> clause with a fully Arden compliant query, can only be constructed on top of READ AS statements. For more information see Sections 11.2.2 and 0.

11.2.1.2 *Examples*

These are valid **read** statements (the portions within curly brackets are arbitrary):

```
var1 := READ {select potassium from results where specimen = `serum`};
var1 := READ last {select potassium from results};
LET var1 BE READ {select potassium from results} WHERE it occurred within the
    past 1 week;
var1 := READ first 3 from {select potassium from results} WHERE it occurred
    within the past 1 week;
LET var1 BE READ {select potassium from results} WHERE it >= 3.4 AND it
    occurred within the past 1 week;
```

11.2.1.3 *Effect*

The effect of the **read** statement is to execute a query, mapping the data in the patient database to a variable that can be used elsewhere in the MLM. The execution of the **read** statement will be institution-specific. The time constraints must be added to whatever other constraints are within the mapping clause, and the aggregation or transformation operator must also be added to complete the query.

11.2.1.4 *Result Type*

The result of a query includes the primary time for each item that is returned (see Section 8.9). If **<aggregation>** is an aggregation operator, then the query returns a single item. If **<aggregation>** is a transformation operator or it is absent, then the query returns a list. Thus even if the query requests an entity that is usually singular, such as the birthdate of the patient, a list is assumed unless an aggregation operator is applied (but the list might contain only a single value, in which case it would be indistinguishable from a scalar). The reason for this is that a patient database may have multiple values for a birthdate; it may be that the last one is assumed to be correct. For example,

```
birthdate := READ last {select birthdate from demographics};
```

11.2.1.5 *Multiple Variables*

A query may return more than one result at a time. This is useful for batteries of tests in order to keep the corresponding tests within one blood sample coordinated. The two versions are equivalent (the parentheses around the where are optional):

```
(<var>, <var>, ...) := READ <aggregation> <mapping> WHERE <constraint>;
LET (<var>, <var>, ...) BE READ <aggregation> (<mapping> WHERE <constraint>);
```

This is the only situation where a "list of lists" is allowed. The where constraint (if any) is applied separately to each of the resulting lists. Queries must always return the same number of elements, with the same primary times.

There may be one or more **<var>** within the parentheses. **<aggregation>**, **<constraint>**, and **<mapping>** are defined as above. The fact that multiple entities are being queried at once is represented in the institution-specific part, **<mapping>**. The **<aggregation>** and **<constraint>** are performed separately on the individual variables; it is institution-defined whether the **<mapping>** returns all the values with matching primary times. For example,

```
/* in this example three anion gaps are calculated */
(Na, Cl, HCO3) := read last 3 from {select sodium, chloride, bicarb from
    electro};
anion_gap := Na - (Cl + HCO3);
```

The order in which read mappings are evaluated is undefined, except that an implementation must guarantee that a read mapping is evaluated before the first time that its value is needed. An implementation may optimize code to avoid executing a read mapping, even if the read mapping has side effects.

11.2.2 Read As Statement

The **read as** statement is very similar to the **read** statement (Section 11.2.1). However, rather than returning query results as a set of lists, where each list represents a collection of values for a particular query field (or column), it returns a single list of objects, each of which consist of named attributes (fields) and values. The attribute names are specified in the **object** declaration, which should have been declared previously (see Section 11.2.17).

```
<var> := READ AS <object-type> <aggregation> <mapping> WHERE <constraint>;
LET <var> BE READ AS <object-type> <aggregation> <mapping> WHERE
    <constraint>;
```

<object-type> is a name which represents an object type declared previously by an **object** declaration (see Section 11.2.17).

```
MedicationDose := object [Medication, Dose, Status];
med_doses := read as MedicationDose
 {select med, dosage, status from client where status != "inactive"};
```

It is often easier to manipulate data in this format, because it allows associated values to stay together when lists of data are appended or otherwise manipulated.

It is up to the MLM author to assure that the implementation-specific contents of the curly braces produces the values to be assigned to attributes, and in the correct order.

The following example shows two ways to retrieve three anion gap values, first using **read** and then using **read as**. Note that the text of the implementation-dependent section (curly braces) did not need to change in this example, although of course this standard does not specify anything about this section. The point here is that the same data is retrieved in each case, but it is just returned in a different form.

```
/* in this example the data to calculate three anion gaps are retrieved */
(Na, Cl, HCO3) := read last 3 from {select sodium, chloride, bicarb from
    electro};
/* using READ AS */
AnionGap := Object [Na, Cl, HCO3];
gaps := read as AnionGap last 3 from {select sodium, chloride, bicarb from
    electro};
```

11.2.2.1 *Read As FHIR Object type*

A special case of the READ AS statement achieved by reading a FHIR object type, which is used to describe an Arden native FHIR query targeting a FHIR repository (see section 0). By defining the <mapping> to be a pre-defined FHIR object the <object-type> field is known to be the same object, thereby the curly braces usually put as mapping are not required.

<var> := READ AS <aggregation> <FHIR-mapping> WHERE <constraint>;The same rules for constraints and aggregations apply in a FHIR Read As statement, only the <object-type> field must not be defined and the <FHIR-mapping> field can only be one of the in section 12.2.1 defined objects supported. These FHIR specific objects do not need to be explicitly defined in the Data Slot, as they are defined within Arden.

```
fhir_observations := READ AS Observation;
fhir_latest_observations := READ AS latest Observation;
fhir_observation_timeframe := READ AS Observation WHERE it occurs within 3
    days;
```

Whenever a FHIR Coding is included in the queries WHERE clause, additionally to the classic String comparison operators the CodeSystem can be compared to a **Valueset** (see Section 9.6.14). Arden Valueset here is another pre-defined object type, meant to hold the URI resolvable information used to retrieve a valueset of logically grouped codes in the network. That resolveable URI is in FHIR approved format (for any further details on Valueset in Arden-FHIR see Section 12.5.1).

```
exam_valueset := NEW Valueset WITH
    [system:="https://fhir.loinc.org/ValueSet", code:= "LL1162-8"];
fhir_observations := READ AS Observation WHERE
    fhir_observations.code.coding.code IS IN exam_valueset;
```

11.2.3 Event Statement

The event statement assigns an institution-specific event definition to a variable. An event can be an insertion or update in the patient database, or any other medically relevant occurrence. The variable is currently used in the evoke slot (see Section 14), as part of the call statement to call other MLMs (see Section 10.2.5), and as a Boolean value in a **logic** or **action** slot. There are two equivalent versions:

```
<var> := EVENT <mapping>;
LET <var> BE EVENT <mapping>;
```

11.2.3.1 *Definitions*

 <var> is a variable that represents the event to be defined. It can only be used in the evoke slot or as part of a call statement.

<mapping> is a valid mapping clause (see Section 7.1.18) which contains the institution-specific event definition. How the event is defined and used is up to the institution.

The variable that represents the event can be treated like a Boolean in the **logic** or **action** slots. The Boolean value of the variable is false until the MLM is called by the referred event.

The **time** operator (see Section 9.17) can be applied to an event variable. It yields the clinically relevant time of the event. This may be different from the **eventtime** variable, which refers to the time that the event was recorded in the database (see Section 8.4.4).

The order in which event mappings are evaluated is undefined, except that an implementation must guarantee that an event mapping is evaluated before the first time that its value is needed.

11.2.3.2 *Example*

```
event1 := EVENT {storage of serum potassium};
```

11.2.4 MLM Statement

The MLM statement assigns a valid mlmname to a variable. That variable is currently used only as part of the call statement to call another MLM, as defined in Section 10.2.5. There are two basic forms (the pairs represent equivalent versions):

```
<var> := MLM <term>;
LET <var> BE MLM <term>;

<var> := MLM <term> FROM INSTITUTION <string>;
LET <var> BE MLM <term> FROM INSTITUTION <string>;
```

11.2.4.1 *Examples*

```
LET MLM1 BE MLM 'my_mlm1';
mlm2 := MLM 'my_mlm2.mlm' FROM INSTITUTION "my institution";
```

11.2.4.2 *Definitions*

<var> is a variable that represents the MLM to be called. It can only be used as part of a call statement.

<term> is a valid constant term as defined in Section 7.1.17. It is the mlmname of the MLM to be called. **mlm_self** (case insensitive) is a special constant that represents the name of the current MLM.

<string> is a valid constant string as defined in Section 7.1.13. If specified, it is the institution name found in the institution slot of the MLM to be called.

If the institution is specified, then a unique MLM is found using the institution name, the mlmname, and the latest version number. If the institution is not specified, then a unique MLM is found using the same institution as the main (calling) MLM, the mlmname, the MLM's validation, and the latest version number. Although the exact form of the version is institution-specific, within an institution it is possible to determine the latest version of an MLM (see Section 6.1.4).

11.2.4.3 *Examples*

```
mlm1 := MLM 'mlm_to_be_called';
mlm2 := MLM 'diagnosis_score' FROM INSTITUTION "LDS Hospital";
```

11.2.5 Argument Statement

The **argument** statement is used by an MLM that is called by another MLM, as defined in Section 10.2.5. If the main MLM passes parameters to the called MLM, then the called MLM retrieves the parameters via the argument statement. The **argument** statements access the corresponding passed arguments. Thus, the first variable <var1> refers to the first passed argument, the second variable <var2>to the second argument, etc.

If there is a mismatch of variables where the number of variables is greater than the number of arguments passed from the CALL, **null** is assigned to the extra left-hand-side variable(s). If the MLM is evoked instead of called, all the arguments are treated as **null** (just like any other uninitialized variable).

There are two basic forms (the pairs represent equivalent version). One receives a single parameter, and the other receives multiple parameters:

```
<var> := ARGUMENT;
LET <var> BE ARGUMENT;
```

```
(<var1>, <var2>, …) := ARGUMENT;
LET (<var1>, <var2>, …) BE ARGUMENT;
```

<var> is a variable that is assigned whatever expression followed **with** in the main MLM's call statement. If there was no such expression, or if the MLM was not called by another MLM, then **null** is assigned.

11.2.5.1 *Example*

In the calling MLM:

```
var1 := CALL my_mlm WITH param1, (item1, item2);
```

In the called MLM, named "**my_mlm**":

```
(arg1, list1) := ARGUMENT;
```

11.2.6 Message Statement

The message statement assigns an institution-specific message (for example, an alert) to a variable. It allows an institution to write coded messages in the patient database (see Section 13.2). There are two equivalent versions:

```
<var> := MESSAGE <mapping>;
LET <var> BE MESSAGE <mapping>;
```

<var> is a variable that represents the message to be defined. It can only be used in a write statement.

<mapping> is a valid mapping clause (see Section 7.1.18), which contains the message definition. How the message is defined and used is up to the institution.

11.2.6.1 *Example*

```
message1 := MESSAGE {pneumonia~23 45 65};
```

11.2.7 Message As Statement

The **message as** statement is very similar to the **message** statement (Section 11.2.6). However, rather than returning a variable, it returns a single object, which consists of named attributes (fields) and values. The attribute names are specified in the **object** statement, which should have occurred previously in the MLM (see Section 11.2.17). If the mapping clause is empty, it may be omitted in this statement. However, it is up to the implementation if a non-empty mapping clause is allowed.

```
<var> := MESSAGE AS <object-type> <mapping>;
<var> := MESSAGE AS <object-type>;
LET <var> BE MESSAGE AS <object-type> <mapping>;
LET <var> BE MESSAGE AS <object-type>;
```

<object-type> is a name which represents an object type declared previously by an **object** statement (see Section 11.2.17).

11.2.7.1 *Example*

```
message_obj := OBJECT [subject, text];
high_PTT_msg := MESSAGE AS message_obj {Elevated PTT};
def_msg := MESSAGE AS message_obj; // default mapping clause
```

11.2.8 Destination Statement

The **destination** statement assigns an institution-specific destination to a variable. It allows one to write a message to an institution-specific destination (see Section 13.2.1). There are two equivalent versions:

```
<var> := DESTINATION <mapping>;
LET <var> BE DESTINATION <mapping>;
```

<var> is a variable that represents the destination to be defined. It can only be used in a write statement.

<mapping> is a valid mapping clause (see Section 7.1.18) that represents an institution-specific destination. How the destination is defined and used is up to the institution.

11.2.8.1 *Example*

In this example, the destination is an electronic mail address:

```
destination1 := DESTINATION {email: user@cuasdf.bitnet};
destination2 := DESTINATION {attending_physician(Pt_id)};
destination3 := DESTINATION {"primary physician email"};
```

11.2.9 Destination As Statement

The **destination as** statement is very similar to the **destination** statement (Section 11.2.8.1). However, rather than returning a variable, it returns a single object, which consists of named attributes (fields) and values. The attribute names are specified in the **object** statement, which should have occurred previously in the MLM (see Section 11.2.17). If the mapping clause is empty, it may be omitted in this statement. However, it is up to the implementation if a non-empty mapping clause is allowed.

```
<var> := DESTINATION AS <object-type> <mapping>;
<var> := DESTINATION AS <object-type>;
LET <var> BE DESTINATION AS <object-type> <mapping>;
LET <var> BE DESTINATION AS <object-type>;
```

<object-type> is a name which represents an object type declared previously by an **object** statement (see Section 11.2.17).

It is up to the MLM author to assure that the implementation-specific contents of the mapping produces the values to be assigned to attributes, and in the correct order.

11.2.9.1 *Example*

```
dest_obj := object [dest_method, recip_name, recip_address];
email_attending := DESTINATION AS dest_obj {Attending Phys Email};
def_destination := DESTINATION AS dest_obj;
```

11.2.10 Assignment Statement

The assignment statement, defined in Section 10.2.1, is also permitted in the data slot.

11.2.11 If-Then Statement

The **if-then** statement, defined in Section 10.2.1.2, is also permitted in the data slot.

11.2.12 Switch-Case Statement

The **switch-case** statement, defined in Section 10.2.3, is also permitted in the data slot.

11.2.13 Call Statement

The **call** statement, defined in Section 10.2.5, is also permitted in the data slot.

11.2.14 While Loop

The **while** loop (with an optional **breakloop** statement), defined in Section 10.2.6, is also permitted in the data slot.

11.2.15 For Loop

The **for** loop (with an optional **breakloop** statement), defined in Section 10.2.7, is also permitted in the data slot.

11.2.16 Interface Statement

The **interface** statement assigns an institution-specific foreign function interface definition to a variable. The **interface** statement permits specification of a foreign function, i.e., a function written in another programming language. Sometimes medical logic requires information not directly available from the

database (via **read** statements). It may be desirable to call operating system functions or libraries obtained from other vendors. A foreign function, when specified, can then be called with the call statement (see Section 10.2.5). Curly braces (**{}**) are used to specify the foreign function. The specification within the curly braces is implementation specific. There are two equivalent versions:

```
<var> := INTERFACE <mapping>;
LET <var> BE INTERFACE <mapping>;
```

<var> is a variable that represents the interface to be defined. It can only be used as part of a call statement.

<mapping> is a valid mapping clause (see Section 7.1.18) which contains the institution-specific event definition. How the function interface is defined and used is up to the institution.

11.2.16.1 *Example*

```
data:
    /* Declares the third-party drug-drug interaction function */
    /* The implementation within the {}-braces shows that a string (char*)
       will be returned */
    /* when the third-party API (ThirdPartyAPI) is used to call */
    /* the drug-drug interaction function (DrugDrugInteraction) */
    /* The function expects that two medicaion strings (char*, char*) will be
       passed */
    func_drugint := INTERFACE {
            char* ThirdPartyAPI:DrugDrugInteraction (char*, char*)
            };
;;
evoke:
;;
logic:
    /* Calls the drug-drug interaction function */
    alert_text := call func_drugint with "terfenadine", "erythromycin";
```

11.2.17 Object Statement

The **object** statement assigns object declaration to a variable. This variable should not be reassigned in another statement, and the variable name becomes the object type name (as used in a **read as** statement (Section 11.2.2) or **new** statement (Section 10.2.8). The object statement permits specification of the attributes and attribute ordering of an object type.

```
<var> := OBJECT "[" <attribute-name-1>, <attribute-name-2> ... "]";
LET <var> BE OBJECT "[" <attribute-name-1>, <attribute-name-2> ... "]";
MedicationDose := OBJECT [Medication, Dose, Status];
```

Object attributes follow the same rules as variable names regarding allowed characters. As with variable names, character case is not significant.

11.2.18 Linguistic Variable Statement

Linguistic variables are used to use fuzzy sets in conjunction with other fuzzy sets in order to define a subset of a value range. Assume a value, stored in the variable parameter, out of an arbitrary interval W. Furthermore, assume three fuzzy sets u_1, u_2, and u_3 over W representing the ranges "low", "middle", and "high". In such a case, it is necessary to save these three fuzzy sets together in a single variable of the type **object** whose fields are named according to the ranges, such as:

```
Range := object [low, middle, high];
Value := new Range;
Value.low := /definition of the fuzzy set u₁ /;
Value.middle := /definition of the fuzzy set u₂ /;
Value.high := /definition of the fuzzy set u₃ /;
```

Whenever a parameter has a low, medium, or high value, it can be evaluated by the following expressions, which provide three truth values, whose sum is truth value 1.

```
Parameter = Value.low;
Parameter = Value.middle;
Parameter = Value.high;
```

To clarify the significance of the fuzzy sets, the keyword **linguistic variable** is used for object declarations where all components are fuzzy data types.

```
RangeOfAge := linguistic variable [young, middleAge, old];
Age := new RangeOfAge;
Age.young := FUZZY SET (0 years, truth value 1), (25 year, truth value 1),
    (35 years, truth value 0);
Age.middleAge := FUZZY SET(25 years, truth value 0), (35 years, truth value
    truth value 1), (55 years, truth value 1), (65 years, truth value 0);
Age.old := FUZZY SET (55 years, truth value 0), (65 years, truth value 1);
```

Now, if the variable myAge is interpreted as the age of a person, **myAge is Age.young** returns a truth value that indicates the degree to which the statement "is the person young" is justified.

11.2.19   New Statement

The **new** statement, defined in Section 10.2.8, is also permitted in the data slot.

11.2.20   Include Statement

The include statement is analogous to the include statement in C-based languages in that indicates an external MLM may be consulted for object, MLM, event, interface variable and resource definitions. The **include** statement references a variable previously assigned in an MLM statement (Section 11.2.4). When object definitions or resource definitions occur in both the local MLM and a remote MLM, the definition in the local scope always takes precedence. If two remote MLMs define objects or resource definitions with the same name or key, the definitions in MLMs referred to later in the local MLM take precedence. The basic form of the statement is

```
INCLUDE <var>;
```

11.2.20.1   *Example*

```
mlm2 := MLM 'my_mlm2.mlm' FROM INSTITUTION "my institution";
INCLUDE mlm2;
```

11.3   Data Slot Usage

The data slot is used to map institution-specific entities to variables used locally in the MLM. Keeping the mappings in one slot facilitates modifying an MLM for use in another institution.

Although the data slot can perform assignment statements and **if-then** statements like the logic slot, it is recommended that most of the logic be left in the logic slot. For example, it would be possible to write an MLM with all its mappings and health logic in the data slot, leaving only a simple conclude statement in the logic slot; but this defeats the purpose of separating the data slot and the logic slot. Assignment statements and **if-then** statements should be used in the data slot only where necessary to support database queries (for example, to calculate a time constraint or to handle details of database semantics, such as handling missing data).

12 FHIR-ENABLED DATA ACCESS

12.1 Introduction

Portability of MLMs has been a challenge since their inception. The use of the { and } characters (known as the curly braces) to encapsulate local calls to an electronic patient data repository has meant that a significant part of each MLM would need to be rewritten when porting the logic to a site served by a different electronic health record (EHR). The Fast Healthcare Interoperability Resources (FHIR) standard has been designed to support the creation of applications that can be shared across EHRs without rebuilding the queries needed to collect and to store data objects. They provide an alternative to the curly braces for accessing and managing data objects.

In order to maintain backwards compatibility, the curly braces will continue to be supported. Arden, version 3.0 provides a syntax for incorporating data access based on FHIR within the Data Slot in Arden. The functionality supported will be that consistent with 1) the role of Arden as a tool for expressing medical decisions focused on the needs of individual patients, 2) the data access capabilities available in the normative, 4.3.0, release of FHIR. As more FHIR capabilities become normative, appropriate syntax and examples will be provided.

12.2 Supported FHIR Resources

Based on FHIR release 4.3.0 (see https://hl7.org/fhir/R4B) Arden supports a limited number of resources, notably those that reflect the types of data historically found in Arden MLMs. A preference is to support normative HL7 specifications, but exceptions are made for data types that appear in MLMs frequently. While the Arden extensions described here reflect the current state of FHIR *resources*, syntax is provided to support access to collections of FHIR *profiles* that may be used to extend the basic FHIR resources for specialized or local use-cases. The HL7 FHIR standard is still in active development and therefore some resources required by Arden have not reached normative status. The associated Arden Syntax may change in future versions of this document.

Arden's approach to accessing data through an initial set of FHIR resources is discussed below. Note that Arden assumes that the decision targeted by an MLM is provided for a single, identified patient and that each MLM is aware of the "primary time" of each data element/object that is queried. The default **patient link** and **primary time** fields for the FHIR resources reviewed here are provided in the table below.

Resource	FHIR Version	Maturity Level	Patient link	Primary time
Patient	4.3.0 - R4B	normative	*patient.identifier*	*patient.meta.lastUpdated*
Observation	4.3.0 - R4B	normative	*observation.subject*	*observation.effectiveDateTime*
Condition	4.3.0 - R4B	Trial use	*condition.subject*	*condition.onsetDateTime*
Encounter	4.3.0 - R4B	Trial use	*encounter.subject*	*encounter.period.start*

12.2.1 Arden-FHIR Objects

Each of the FHIR resources supported by Arden (either from this standard or specialized implementations) must correspond to a pre-defined Arden Object. The object must contain all fields as stated by its FHIR documentation, and the field type will generally (e.g., by READ AS statements) be mapped to the closest Arden data type (<Number>, <Time>, <Boolean> or in any other case <String>). This pre-defined object must be available to each MLM's data slot without being explicitly defined. These objects do serve as standardized data model for FHIR resources in Arden and further identify any FHIR-specific action (e.g., a FHIR **read statement** must have a FHIR object as mapping type, if it doesn't, the statement shall be interpreted as an ordinary curly-braces **read statement**).

12.3 Patient-Oriented

The focus of the Arden Syntax is the delivery of suggested clinical decisions for individual patients. Therefore, all FHIR API calls will be restricted by the resource's **Patient link** (Patient compartment in FHIR REST calls). To support this, Arden contains a predefined object that will represent the default patient used to trigger the MLM. This object is an abbreviated copy of the FHIR Patient resource and will contain core patient information including the patient's ID (**Patient.Identifier**), the patient's status (**Patient.active**) the patient's date of birth (**Patient.birthdate**), and the patient's gender (**Patient.gender**). The **Patient** data object is provided in the Arden execution environment and automatically available to the logic in an MLM.

A patient can be identified, and the default **Patient** information can be instantiated in one of two ways. When one or more MLMs are called <u>directly</u> by a process, the process will provide the required **Patient** data object to the execution engine. Its attributes will be instantiated as a part of the calling process. When an MLM is invoked through the data-drive mechanism, the executing environment will use patient identifiers associated with the invoking data element to populate the attributes in the **Patient** object.

12.4 Primary Time from FHIR Resources

The Arden Syntax specifies that each data element/object used in an MLM has a ***primary time***. A primary time is required for most of the Arden temporal operators to function correctly. Primary times associated with FHIR data objects should reflect the effective point in time for that FHIR resource. This is the time when the data was or first became clinically relevant. For the Patient resource its field *patient.meta.lastUpdated* should be used; for the Observation resources *effectiveDateTime* is used; for Condition resources, the *condition.onsetDateTime* can be used; and for Encounter resources typically the field *period.start* contains the primary time. These fields are typically initialized in any new FHIR object, but in case it should be empty, *meta.lastUpdated* (present in any FHIR resource Object) shall be used as a substitute.

12.5 Pre-Defined Resources

12.5.1 Pre-defined Objects

Any Arden objects available through FHIR are available in the Data Slot and must not be defined explicitly (see Section 12.2.1). Moreover, these Arden-FHIR objects must be used to activate standard data model access, including native queries on FHIR repositories with the READ AS statement.

Another important object for FHIR-enabled data access is the Arden **Valueset** object-type. It is essential in defining FHIR-supported valueset queries as part of the READ AS WHERE statement, for CodeSystem type fields in Arden-FHIR objects (see Section 9.6.14). The following example demonstrates how the Valueset object is defined. This definition must not be inside an MLM, the Valueset object is already pre-defined:

```
/* How a Valueset definition would look like */
LET Valueset BE OBJECT ["system", "code"];
```

12.5.2 Environment Variables

When starting a FHIR query to an external data source (FHIR repository) some information needs to be provided explicitly in order for this READ statement to succeed. It can be arduous to provide all reference data strings for every query (such as the network destination of your FHIR repository) or write out every static terminology coding system for each MLM (e.g., http://snomed.info/sct for SNOMED), therefore a set of commonly used environment variables is available in the Data Slot of each MLM.

Variables might be overwritten before the MLM is invoked, so the default values provided in this section are only suggestions. A number of reasons can cause an environment variable to be overwritten, for example, if it points to a public URL that has changed, a newer version of FHIR specifies another URL to be used or the local implementing network space uses another reference than the one provided. In case no

suggested value is provided here the variable will still have a default value in each MLM, but it is up to the implementer to provide this (see the Implementation Guide) and cannot be predicted here.

These variables can be overwritten if necessary (especially for My_FHIR_Repository this is often the case) and the variable names are all permanently reserved, meaning that you cannot introduce a new, unrelated, variable of the same name.

Variable Name	Suggested default value	Use
My_FHIR_Repository	-	Target FHIR repository, which is the data source for READ and WRITE statements. Override with any FHIR repository base URL
LOINC_Valuesets	"http://loinc.org/vs/"	Combine with LOINC valueset codes to create a code.coding.code search parameter, including all coded values of this valueset
NLM_Valuesets	"https://vsac.nlm.nih.gov/valueset/"	Combine with NLM valueset codes to create a code.coding.code search parameter, including all coded values of this valueset
NLMRX	"http://www.nlm.nih.gov/research/umls/rxnorm"	*code.coding.system* value for US NLM RxNorm coded fields used in FHIR
LOINC	"http://loinc.org"	*code.coding.system* value for LOINC coded fields in FHIR
SNOMEDCT	"http://snomed.info/sct"	*code.coding.system* value for Snomed CT coded fields in FHIR
ICD9CM	"http://hl7.org/fhir/sid/icd-9-cm"	*code.coding.system* value for ICD 9 (US) coded fields. Be aware of other versions and locales; refer to FHIR documentation
ICD10CM	"http://hl7.org/fhir/sid/icd-10-cm"	*code.coding.system* value for ICD 10 (US) coded fields. Be aware of other versions and locales, refer to FHIR documentation
ICD11CM	"http://hl7.org/fhir/sid/icd-11-cm"	*code.coding.system* value for ICD 11 (US) coded fields. Be aware of other versions and

		locales, refer to FHIR documentation
AMACPT	"http://www.ama-assn.org/go/cpt"	*code.coding.system* value for [AMA CPT](#) coded fields used in FHIR
ISO11073_10101	"urn:iso:std:iso:11073:10101"	*code.coding.system* value for medical device codes by [ISO 11073-10101](#) (used in FHIR)

Some of these variables locate services in the network where the MLM is executed (e.g., My_FHIR_Repository) while others represent identifying values in the FHIR ecosystem, used to associate codes with their terminology/ontology system (e.g., SNOMEDCT or ISO11073_10101). Those variables may be overwritten and can be used without restriction to reference [CodeSystems](#) inside the local FHIR repository.

My_FHIR_Repository is the most essential environment variable, and the only irreplaceable, because its value will be used in locating the FHIR repository on which all READ AS queries are executed. Its value might be overwritten to target a different FHIR repository than the MLM default, and thereby different repositories can be accessed by different MLMs (even if they have the same default URL value); Overwriting FHIR repository URL example:

```
LET My_FHIR_Repository BE "https://fhir.mydomain.org/R4B";
```

Variables pointing to valueset URLs are intended to be used when defining a Valueset object (see Section 12.5.1). Used in the Valueset.system field, they represent the expandable URL needed to create a valueset URL in FHIR read as statements.

```
LET My_LOINC_Valueset BE NEW Valueset WITH [system:=LOINC_Valueset, code:="LL7701-1"];
LET observation_with_LOINC BE READ AS Observation WHERE
observation_with_LOINC.code.coding.code IN My_LOINC_Valueset;
```

12.5.3 FHIR Valueset type variable

A valueset variable, however, defines a constructed absolute URL which, when a code of this system is appended, must be resolved using a compatible **FHIR Valueset** resource. Some terminology authorities already provide such an interface (these are listed above and may be used seamlessly in Arden). If a custom variable is used to point at a custom valueset service it can contain only a string of the full URL pointing to the basic valueset service path (also, resolving any valueset code to a compatible **FHIR Valueset** resource). Be aware that some terminology authorities require payment and authentication for the use of their services. Compliance with this is the responsibility of the Arden Implementer and can, if neglected, cause the FHIR valueset query to fail.

12.5.3.1 *Example: Custom Valueset definition*

A Valueset is accessible through the URL [https://localhost/terminology/fhir/vs/4467-1](#).

This Valueset URL contains two parts: The basic valueset service path (also referred to as "system") **https://localhost/terminology/fhir/vs/** and the valueset code **4467-1.**

To declare a variable for this valueset for use in a READ AS … WHERE … statement, declare a **Valueset** type variable and assign it the desired code with the service path:

```
LET My_Terminology_Server BE "https://localhost/terminology/fhir/vs/";
LET Custom_HbA1c_Codes BE NEW valueset WITH [system:=My_Terminology_Server,
code:="4467-1"];
```

12.6 Filter Parameters – The WHERE Clause

Normally when reading a FHIR resource object the Arden Syntax READ AS … WHERE … operation will be used. This command fetches one or more FHIR resources as Arden Objects from the remote repository (pointed to in the environment variable *My_FHIR_Repository*) and applies the WHERE clause conditions as a filter for this request. The filter functionality is considered a core pillar of medical resources represented in FHIR, as it allows the MLM writer to specify individually what to retrieve (e.g., Type of medical procedure, date of an encounter, diagnosis, …).

On the other hand, the WHERE clause remains conditional for FHIR READ statements, therefore it might just be left out. If no filter parameters are defined in a LET … READ AS statement, then a list of all resources (of the specified type) is requested from the repository. As with every FHIR READ statement, the result will still be implicitly filtered by the base patient – so only resources subjecting the MLM's base patient are returned.

An implementer may choose to expand the set of supported filter parameters in a custom profile, but in order to comply with the Arden standard, a minimum set of query parameters of each FHIR resource should be implemented.

Below the Arden-FHIR object fields and corresponding Arden data types available in the WHERE clause are listed. Be aware that each of these fields will be supported by compliant Arden implementations, but additional filter parameters can be available depending on the customized profile implemented by an Arden MLM interpreter. A two-stage filtering process will be necessary in some cases in which a set of data objects, retrieved using FHIR search parameters, will be secondarily filtered using additional restrictions from the Arden WHERE clause.

12.6.1 FHIR in the READ AS … WHERE … Statement Part

The main objective of using FHIR-compatible statements in an MLM's data slot is to declare a variable as Arden-FHIR object and fill it with data read from a FHIR repository. With the following schematic a variable declaration (LET statement) can be structured to target a FHIR repository, whereas the general structure of a READ AS statement is used in respect with the special FHIR rule (see Sections 11.2.1 and 11.2.2). For complete examples refer to the example section below:

```
/* Most basic request: Every field from the FHIR resource object is read. No other
filters than the implicit base patient is applied */

LET <variable-name> BE READ AS <FHIR-object-type>;

/* Read a variable and map fields from the FHIR object to custom variable fields to
increase readability of that variable */

LET <variable-name>[<variable-field-name>, …] BE READ AS <FHIR-object-type>[<field-
name>, …];

/* Read not all FHIR resources in one sitting, but select only the latest (most
recent clinically relevant time) */

LET <variable-name> BE READ AS LATEST <FHIR-object-type>;

/* Add the WHERE clause to a mapped FHIR object. Any statement in the WHERE clause
is a Boolean operation and specifies a filter directly applied to the FHIR
repository */

LET <variable-name>[<variable-field-name>, …] BE READ AS <FHIR-object-type>[<field-
name>, …] WHERE <variable-name>.<variable-field-name> = <filter-value> <<n:logic-
operator> <n:comparison-operator>;
```

12.6.2   AND, OR, NOT Operations

Arden Syntax condition operators AND, OR and NOT are fully supported with FHIR object READs as well. The standard operation, AND, can be used to add different filter parameters on one FHIR resource, further restricting one search. The OR operator may be used to widen the search, either on the same or different filter parameters.

12.6.3   Base Resource

Each FHIR resource queryable by Arden so far is based on the abstract Base resource which provides some skeletal fields present in every final resource listed below. This Base resource is normative and not expected to change in future versions of this document. The Base resource's query parameters however are in trial use. The parameters implemented in Arden are valid for FHIR repositories conforming to the supported FHIR version in this document. Query parameters described for the base resource are available in every other resource, although it is **not possible to query a Base resource itself**, as it does not contain any clinical knowledge (added by final resources such as Encounter, Observation or Patient).

FHIR query parameter	Data type	Description
Language	Code (preferred one of CommonLanguages)	Language of this FHIR resource
meta.lastUpdated	Time (only the Date is used)	When this FHIR resource was last changed

12.6.4   Encounter Resource

The FHIR Encounter resource is still in trial use. It is expected to change in future versions of this document. It is included because of the frequent appearance of component data types in historical MLMs. Its query parameters are in trial use as well, for both these reasons the parameters implemented in Arden are valid for FHIR repositories conforming to the supported FHIR version in this document.

FHIR query parameter	Data type	Description
Status	Code (must be any of EncounterStatus)	Current status in this encounter. One of EncounterStatus
Class	String (Value based on extensible ActEncounterCode)	Type of patient encounter (e.g., Ambulatory, virtual, …). One of ActEncounterCode
Period	Time (query for an encounter which start/end time includes this)	Between start and end time of this encounter
Length	Duration (any in days, other formats will be implicitly converted)	Duration of days this encounter lasted

reasonCode.coding.code / *reasonCode.coding.system*	String (of *code* and/or *system* present in an encounter)	Preferably SNOMED code explaining why this encounter takes place
reasonReference (of Condition or *Observation)*	String (*condition.identifier* or *observation.identifier*)	If the reason for this encounter lies in an **Observation** or **Condition**
diagnosis.condition (of Condition)	String (*condition.identifier*)	A diagnosis **Condition** relevant to this encounter
partOf (of Encounter)	String (*encounter.identifier*)	The Encounter this is a part of

12.6.5   Observation Resource

The FHIR **Observation** resource is normative and therefore not expected to change in future versions of this document. Future versions should remain backward compatible. The **Observation's** query parameters however are in trial use and the parameters implemented in this version of Arden are valid for FHIR repositories conformant with the supported FHIR version in this document.

FHIR query parameter	**Data type**	**Description**
Status	Code (must be any of ObservationStatus)	Current status of this observation
category.coding.code / *category.coding.system*	String (of *code* and/or *system* present in an observation)	Preferably Observation Category Code classifying the type of an observation
code.coding.code / code.coding.system	String (of *code* and/or *system* present in an observation)	Any medical coding (LOINC, SNOMED, etc.) specifying the observation type
encounter (of Encounter)	String (*encounter.identifier*)	This observation is made and linked to a healthcare event
effectiveDateTime	Time	Clinically relevant single time this observation took place
effectivePeriod	Time (query for an encounter which start/end time includes this)	Clinically relevant time period, a query will provide one single time and selects any Observation whose effectivePeriod includes this timestamp
valueQuantity.value / valueQuantity.unit */ valueQuantity.system*	Numeric (*value*) and String (*unit* and *system* of unit)	Clinically relevant observation value (numerically) of a given unit (optional) and unit system (optional)

valueString	String	Textual representation of an observations clinically relevant value
valueCodeableConcept.coding.code / valueCodeableConcept.coding.system	String (value as *code* and/or *system* present in an observation)	Any codable concept representing a clinically relevant observation value
valueDate	Time	A specific date representing the clinically relevant observation value
component.code.coding.code / component.code.coding.system	String (of *code* and/or *system* present in an observation)	A component, or single part, this observation is composed of. The *component.code* field represents the specific clinical type similar to *observation.code*
component.valueCodeableConcept.coding.code / component. valueCodeableConcept.coding.system	String (value as *code* and/or *system* present in an observation)	A component, or single part, this observation is composed of. The *component.valueCodeableConcept* field represents a medical observation as codable concept similar to *observation.valueCodeableConcept*
component.valueQuantity.value / component.valueQuantity.unit / component.valueQuantity.system	Numeric (*value*) and String (*unit* and *system* of unit)	A component, or single part, this observation is composed of. The *component.valueQuantity* field is a numerical clinical observation value similar to *observation.valueQuantity*

*Note that an observation can have at most one of the mutual exclusive fields valueQuantity, valueString, valueConcept *or* valueDate.

12.6.6   Condition Resource

The FHIR Condition resource remains in trial use. Its access may change in future versions of this document. Its query parameters are in trial use as well. For both these reasons, the parameters implemented in Arden are valid for FHIR repositories conformant with the supported FHIR version in this document.

FHIR query parameter	**Data type**	**Description**
clinicalStatus.coding.code	Code (must be any of ConditionClinicalStatus)	Current status of this condition
category.coding.code / category.coding.system	String (of *code* and/or *system* present in an observation)	Might be one of Condition_Category_Code or an extension, classifying the type of an observation

code.coding.code / code.coding.system	String (of *code* and/or *system* present in an observation)	Any medical coding (LOINC, SNOMED, etc.) specifying the observation type
subject (of Patient)	String (*patient.identifier*)	Who has this Condition?
encounter (of Encounter)	String (*encounter.identifier*)	This Condition is created as part of an Encounter
onsetAge.value / onsetAge.unit / onsetAge.system	Numeric (*value*) and String (*unit* and *system* of unit)	Of this clinical condition, the estimated age (numeric) of a specific unit (optional, unit and system String)
onsetDateTime	Time	Clinically relevant date and time this condition occurred
onsetString	String	Other, textual, representation of this condition's occurrence

12.6.7   Patient Resource

The FHIR Patient resource is normative. Future versions should remain backward compatible. The **Patient's** query parameters however are in trial use and the parameters implemented in this version of Arden are valid for FHIR repositories conformant with the supported FHIR version in this document.

FHIR query parameter	**Data type**	**Description**
Gender	Code (must be any of AdministrativeGender)	Gender of this Patient
birthdate	Time (only the Date is used)	Individual date of birth
deceasedDateTime	Time	Time and date of clinical death for this Patient
Name	String (Matches any one of the fields *name.family, name.given, name.prefix, name.suffix* or *name.text*)	A name associated with this Patient
Address	String (Matches any of the fields *address.line, address.city, address.district, address.postalCode, address.state, address.country* or *address.text*)	One or more addresses of this Patient
link.other	String (*patient.identifier*)	Link to a related Patient

12.7 Examples

The examples below illustrate access to URL-based services that provide the context for FHIR data access. These include a repository for resource definitions, a terminology service, and a service for storing and retrieving clinical data elements. Defaults are specified at execution-engine startup and need not be referenced within the MLM. For access to non-defaulted services, addresses can be provided within the MLM. Non-defaulted service addresses are referenced in the Data Slot using the LET command.

For the following examples, assume a patient with Patient.ID equals 1234567, **Patient.active** equals True, **Patient.birthdate** equals 1962-10-18, and **Patient.gender** equals male.

12.7.1 Service/Resource Definitions

An Arden implementation will have a default terminology server, data repository, and source for resource definitions (see Section 12.5.2). In cases where other/additional instances of these services are needed, they are declared using the LET statement.

12.7.1.1 *Examples: Define service addresses for terminology and clinical data (FHIR repository). These definitions are used to make non-default services available.*

```
/*defining a terminology server to use for value sets and individual codes (for
    cases where the terminology server is not defaulted*/
LET My_Terminology_Server BE "https://local_or_distant_terminology_server.org/";

LET SNOMEDCT_Valuesets BE "http://snomed.info/sct/fhir/vs";

/*defining a data server (for cases where the data server is not defaulted)*/

LET My_FHIR_Repository BE "https://local_or_distant_FHIR_repository.org/";
```

12.7.2 Value Sets

12.7.2.1 Value Sets represent lists of codes from a particular terminology service. For Value Sets from the any terminology service, the LET command assigns a local variable as Valueset object, storing the terminology service URL and valueset identifying code (see Section 12.5).

12.7.2.2 *Example: Define a variable representing a value set from a valueset service.*

```
LET Diabetic_Diagnostic_codes BE NEW Valueset WITH [system:= "
https://www.nlm.nih.gov/fhir/valueset",
code:="2.16.840.1.113883.3.464.1003.103.11.1002"];

LET HbA1c_Test_Codes BE NEW Valueset WITH [system:=LOINC_Valuesets, code:= "LG51070-
7"];
```

12.7.2.3 *Example: Define a valueset variable and use it in a READ statement as WHERE clause.*

```
LET HbA1c_Test_Codes BE NEW Valueset WITH [system:=LOINC_Valuesets, code:= "LG51070-
7"];

LET Latest_HbA1c[exam] BE READ AS LATEST Observation[code.coding.code] WHERE
Latest_HbA1c.exam IN HbA1c_Test_Codes;
```

12.7.2.3.1 *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Observation?subject={Patient.ID}&status
=final&code:in=http://loinc.org/vs/LG51070-7
```

12.7.3 Observation

Much of the stored clinical data that can be represented in FHIR is found in the FHIR Observation. A variety of result types are available and the *effectiveDateTime* is assigned as the *primary time*.

12.7.3.1 *Example: Find latest Observation with LOINC code Hemoglobin A1c.*

```
LET Latest_HbA1c[status, codingsystem, exam] BE READ AS LATEST Observation[status,
code.coding.system, code.coding.code] WHERE Latest_HbA1c.status = "final" and
Latest_HbA1c.codingsystem = LOINC and Latest_HbA1c.exam  = "LG51070-7";
```

12.7.3.1.1 *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Observation?subject={Patient.ID}&status
=final&code=http://loinc.org|LG51070-7
```

12.7.4 Condition

The Condition resource is used to record detailed information about a condition, problem, diagnosis, or other concept that is found in a patient's problem list, diagnostic summary, of similar component of the patient record. A condition is generally recorded through a *CodeableConcept* identifying a coding system and code for the condition. The *onsetDateTime* is typically assigned as the *primary time*. If this is not available, the primary time can be calculated from the *onsetAge*, or set to the beginning of the *onsetPeriod* or the *onsetRange*. In cases where the period or range is relevant, this should be queried separately to place the *start* and *end* date and time in user defined variables.

12.7.4.1 *Example: Find latest Condition of diagnosed diabetes (as LOINC code).*

```
LET Diabetic_Diagnosis[category, codingsystem, code] BE READ AS LATEST
Condition[category, code.coding.system, code.coding.code] WHERE
Diabetic_Diagnosis.category = "encounter-diagnosis" and
Diabetic_Diagnosis.codingsystem = LOINC and Diabetic_Diagnosis.code = "45636-8";
```

12.7.4.1.1 *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Condition?subject={Patient.ID}&status=f
inal&code=http://loinc.org|45636-8
```

12.7.5 Encounter

The Encounter resource wraps up the Patients lifecycle from pre-admission, an encounter (digital, ambulatory, private practice, …) and eventual admission and discharge for inpatient encounters. An encounter resource by itself can have a wide scope of application, the actual fields used in this FHIR resource can depend heavily on the implementer. However, the *Status* and *Class* fields are expected to be present as they fundamentally define the resource and tell the recipient which structure his data has.

12.7.5.1 *Example: Find latest ambulatory Encounter caused by a history of diabetes (as SNOMED-CT code).*

```
LET Diabetic_Ambulatory_Encounter[status, cause_system, cause_code, typeOfEncounter,
admitted] BE READ AS LATEST Encounter[status, reasonCode.coding.system,
reasonCode.coding.code, class.code, period.start] WHERE
Diabetic_Ambulatory_Encounter.status = "finished" AND
Diabetic_Ambulatory_Encounter.typeOfEncounter = "AMB" AND
Diabetic_Ambulatory_Encounter.cause_system = SNOMEDCT AND
Diabetic_Ambulatory_Encounter.cause_code = "161445009";
```

12.7.5.1.1 *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Encounter?subject={Patient.ID}&status=f
inal&class=|AMB&reason-code=http://snomed.info/sct|161445009
```

12.7.6   Patient

As MLMs are invoked based on a Patient event and each FHIR resource must be related to that base patient the plain Patient object is of limited use. It is currently supported to retrieve full patient information for the base or a related patient.

12.7.7   AND Parameter

Further restrict one search by multiple filter parameters of the same FHIR resource object, connected by the AND operator. A FHIR result to this assignment needs to match all parameters defined.

12.7.7.1   *Example: Retrieve an Observation by its status AND code.*

```
LET Latest_HbA1c[status, exam] BE READ AS LATEST Observation[status,
code.coding.code] WHERE Latest_HbA1c.status = "final" AND Latest_HbA1c.exam =
"55454-3";
```

12.7.7.1.1   *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Observation?subject={Patient.ID}&status
=final&code=|55454-3
```

12.7.8   OR Parameter

Expand the search scope by including multiple parameters connected by an OR statement. If those are of the same type, or a list of multiple values, the FHIR query will look slightly differently than for those cases where different parameters are defined. In either case, the FHIR search result will select each resource match at least one of the given parameters.

12.7.8.1   *Example: Retrieve an Observation by either of its codes.*

```
LET Latest_HbA1c[status, codingsystem, exam] BE READ AS LATEST Observation[status,
code.coding.system, code.coding.code] WHERE Latest_HbA1c.exam = "44331" OR
Latest_HbA1c.exam = "5432-9";
```

12.7.8.1.1   *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Observation?subject={Patient.ID}&code=|
44331,|5432-9
```

12.7.8.2   *Example: Retrieve an Observation by its code OR clinical method.*

```
LET Latest_HbA1c[status, exam_interpretation, exam] BE READ AS LATEST
Observation[status, interpretation, code.coding.code] WHERE
Latest_HbA1c.exam_interpretation = "abnormal" OR Latest_HbA1c.exam = "5432-9";
```

12.7.8.2.1   *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Observation?subject={Patient.ID}&_filte
r= method eq |272394005 or code eq |54342-9
```

12.7.9   NOT Parameter

The NOT parameter works as intended with each Arden READ filter parameter, able to negate this specific condition in the FHIR filter as well.

12.7.9.1   *Example: Retrieve an Observation which is not final yet.*

```
LET Latest_HbA1c[status, codingsystem, exam] BE READ AS LATEST Observation[status,
code.coding.system, code.coding.code] WHERE Latest_HbA1c.status IS NOT "final";
```

12.7.9.1.1 *FHIR expression:*

```
GET
https://local_or_distant_FHIR_repository.org/Observation?subject={Patient.ID}&status
:ne=final
```

13 ACTION SLOT

13.1 Purpose

Once the MLM has concluded that the condition specified in the logic slot holds true, the action slot is executed, performing whatever actions are appropriate to the condition. Typical actions include sending a message to a health care provider, adding an interpretation to the patient record, returning a result to a calling MLM, and evoking other MLMs. Good programming practice is for an MLM's action slot to contain only return statements, or to contain only call and write statements. If an MLM is called from an action slot (see Section 13.2.5) or evoked by an external event (see Section 14), the only effect of a return statement is to terminate execution of the action slot.

13.2 Action Slot Statements

13.2.1 Write Statement

The **write** statement is the main statement in the action slot. It sends a text or coded message (for example, an alert) to a destination. It has several forms:

```
WRITE <expr>
WRITE <expr> AT <destination>
WRITE <message>
WRITE <message> AT <destination>
```

<expr> is any valid expression, which usually contains text to be read by the health care provider or variables defined in the logic slot.

<destination> is a destination variable as defined in Section 11.2.8. The format and implementation of the destination is institution-specific. Typical destinations include the patient record, a printer, databases, and electronic mail addresses. When the destination is omitted, the message is sent to the default destination. This is generally the health care provider or the patient record, but the implementation is institution-specific.

<message> is a message variable as defined in Section 11.2.6. The message variable permits institutions to write institution-specific coded MLM messages to databases that will not accommodate the **<expr>** form.

<expr> is often a string. If a particular implementation or deployment of Arden Syntax needs to use XML to structure messages, a string expression can be used to compose this message. Appendix X1 shows the recommended DTD for structured messages.

The effect of the write statement is to send the specified message either to the default destination (which is usually a health care provider or the patient record) or the destination that is specified.

Within a single MLM, the effect of grouping write statements is unspecified, and depends on the implementation of the syntax.

If an MLM is called by another MLM's action block (see Section 13.2.5), its write statements are output as a separate group from the calling MLM's. However, the order of the groupings is unspecified and depends on the implementation of the syntax.

Note that embedding the AT operator (Section 9.17.3) in a WRITE statement can introduce ambiguity. The use of the operator in this context is implementation-specific.

13.2.1.1 *Examples<expr>*

In these examples, **serum_pot** is a variable assigned in the logic slot, **email_dest** is a destination variable defined in the data slot, and **a_message** is a message variable defined in the data slot.

```
WRITE "the patient's potassium is" || serum_pot;
WRITE "this is an email alert" AT email_dest;
WRITE a_message;
```

13.2.1.2 *Examples<message>*

An institution can store coded messages without using the message variable. For example, the following message could be stored not as a free text string but as a unique code that symbolizes the message along with a single field that holds the serum potassium value, which is variable:

```
WRITE "the patient's potassium is " || serum_pot;

WRITE CK0023 || serum_pot;
```

CK0023 would be the institution-specific code representing "**the patient's potassium is**".

The message must be explicitly assigned to the institution-specific code before the code is used in a write statement. Generally, this assignment should take place in the data slot.

13.2.2 Return Statement

The return statement is used in MLMs that are called by other MLMs. It returns a result back to the calling MLM; the result is assigned to the variable in the call statement (see Section 10.2.5). One or more results can be returned by the MLM. Its form is:

```
RETURN <expr>;
RETURN <expr>, ..., <expr>;
```

<expr> is any valid expression, which may be a single item or a list. Primary times are maintained.

When a return statement is executed, no further statements in the MLM are executed.

13.2.2.1 *Examples:*

```
RETURN (diagnosis_score, diagnosis_name);
RETURN diagnosis_score, diagnosis_name;
```

The first example returns one expression, which is a list. The second example returns two expressions.

13.2.3 If-then Statement

The **if-then** statement, defined in Section 10.2.1.2, is also permitted in the action slot.

13.2.4 Switch-Case Statement

The **switch-case** statement, defined in Section 10.2.3, is also permitted in the action slot.

13.2.5 Call Statement

The **call** statement in the action slot permits an MLM to call other MLMs conditionally based upon the conclusion in the logic slot. It is similar to the **call** statement in the logic slot defined in Section 10.2.5; the arguments can be accessed with the **argument** statement in Section 11.2.5. Given an mlmname, the MLM can be called directly with an optional delay. Given an event definition, all the MLMs that are normally evoked by that event can be called with an optional delay. If the call statement is used to evoke an event, any arguments are ignored. Its forms are:

```
CALL <name>;
CALL <name> DELAY <duration>;
CALL <name> WITH <expr>;
CALL <name> WITH <expr> DELAY <duration>;

CALL <name> WITH <expr>, ..., <expr>;
CALL <name> WITH <expr>, ..., <expr> DELAY <duration>;
```

<name> is an identifier that must represent either a valid MLM variable as defined by an MLM statement in the data slot (see Section 11.2.4), or a valid event variable as defined by an event statement in the data slot (see Section 11.2.3).

<duration> is a valid expression whose value is a duration.

13.2.5.1   *Operation*

If **<name>** is an MLM variable, then when the main MLM terminates, the named MLM is called. If **<name>** is an event variable, then all the MLMs whose evoke slots refer to the named event are executed (see Section 14.1). If a delay is present, then the execution of the called MLMs is delayed by the specified duration. Whereas the call statement in the logic slot is synchronous, the call statement in the action slot is asynchronous. The order of execution of called MLMs is implementation dependent.

13.2.5.2   *Example*

(where **mlmx** has been assigned a suitable value in the data slot, say by **mlmx := MLM 'my_mlm'**):

```
        CALL mlmx DELAY 3 days;
```

13.2.6   While Loop

The **while** loop (with an optional **breakloop** statement), defined in Section 10.2.5.10, is also permitted in the action slot

13.2.7   For Loop

The **for** loop (with an optional **breakloop** statement), defined in Section 10.2.6.1, is also permitted in the action slot.

13.2.8   Assignment Statement

The **assignment** statement, defined in Section 10.2.1, is also permitted in the action slot. Note that with Arden versions prior to 2.5, **assignment** statements were not permitted in the action slot. This capability was added in 2.5 to allow increased flexibility for things like **while** loops, which are not usable without assignment. MLM authors should remember to keep the logic to the logic slot, as much as possible. Refer to Section 13.3, below, for details.

13.3   Action Slot Usage

The action slot is usually simple, containing a single message to be written or a single value to be returned to a calling MLM. Multiple actions can be performed by listing several action statements. The slot can be made more complex by using its if-then statement to select among alternative actions. While this is useful, it is recommended that the amount of health logic in the action slot be kept to a minimum.

14 EVOKE SLOT

14.1 Purpose

The evoke slot defines how an MLM may be triggered. An MLM may be triggered by any of the following:

14.1.1 Occurrence of Some Event

For example, on the storage of a serum potassium value in the patient database, in order to check for values that are far out of range.

14.1.2 A Time Delay After an Event

For example, five days after ordering gentamicin for a patient, in order to check renal function.

14.1.3 Periodically After an Event

For example, every five days after ordering gentamicin for a patient, in order to check renal function over a period of time.

14.1.4 A Constant Time Trigger

For example, on 07-27-2007 at 12:00:00.

14.1.5 A Constant Periodic Time Trigger

For example, start on Friday at 18:00:00, trigger again every week for one year.

14.2 Events

Events are distinct from data. An event may be an update or insertion in the patient database, a medically relevant occurrence, or an institution-defined occurrence. Examples include the storage of a serum potassium level, the ordering of a medication, the transferring of a patient to a new bed, and the recording of a new address for a patient.

14.2.1 Event Properties

The main attribute of an event is the time that it occurred, which must be an instant in time. Events have no values. Note the distinction between events and data. Data have values and have primary times, which are the times that are medically most relevant. For example, a serum potassium result may have a value of 5.0 and a primary time that is the time that it was drawn from the patient. But the **storage of serum potassium** event has no value, and its time is the time that the potassium was stored in the patient database.

14.2.2 Time of Events

The **time of** operator (see Section 9.17) applied to an event results in the time that the event occurred. For example, **time of storage_of_potassium** returns the time that the potassium was stored. This value might be different from the time of the corresponding data value that is retrieved by a read mapping (the data value typically uses a clinically relevant time, which would often be different from the time of storing the data). **Eventtime** (see Section 8.4.4) is the time of the event that evoked the MLM.

14.2.3 Declaration of Events

Events are declared in the data slot as defined in Section 11.2.3.

14.3 Evoke Slot Statements

14.3.1 Simple Trigger Statement

A **simple trigger** statement specifies an event or a set of events. When any of the events occurs, the MLM is triggered. Its form is:

```
<event-expr>
```

<event-expr> is an expression that contains only event variables as defined in Section 11.2.3, the **or** operator (see Section 9.4.1), the **any** operator (see Section 9.12.13), and parentheses. The keyword **call** may also be present, to indicate that the MLM may be called by another MLM.

14.3.2 Operation

Although events do not have values, they are used in this statement as if they were syntactically Boolean. Thus one ends up with a statement like this: **event1 OR event2 OR event3**. The MLM is triggered whenever an event occurs and any of the evoke statements evaluate to **true**. If more than one event occurs, the MLM may be triggered. No additional trigger criteria must be satisfied for the MLM to be evoked.

14.3.2.1 *Examples*

In the following examples, all the variables are event variables defined in the data slot.

```
penicillin_storage
penicillin_storage OR cephalosporin_storage
ANY OF (penicillin_storage, cephalosporin_storage, aminoglycoside_storage)

data:
   penicillin_storage := event {store penicillin order};
   cephalosporin_storage := event {store cephalosporin order};
;;
evoke:
   penicillin_storage OR
   cephalosporin_storage;;
```

14.3.3 Delayed Event Trigger Statement

A **delayed event trigger** statement permits the MLM to be triggered some time after an event occurs. It is of this form:

```
<time-expr> AFTER TIME [OF] <event>
```

<time-expr> is an expression that contains only times expressed as one of the following.

- time constants (see Section 7.1.9),

- as time-of-day constants applied to the at operator in combination with a day-of-week keyword or the reserved words **today,** and **tomorrow** using the **attime** reserved word to combine a day-of-week with a time-of-day in the form <day of week> ATTIME <time of day>

- a duration constant formed by using a number constant with a duration operator

combined using the OR keyword

<event> is an event variable.

<day of week> is a day-of week-variable (see Section 8.12) or the reserved words **today** or **tomorrow.**

<time of day> is a time-of-day variable (see Section 8.11)

For example:

```
TODAY ATTIME 15:00 AFTER TIME OF penicillin_storage
```

The MLM execution is delayed until 15:00 of the day the penicillin_storage event occurs. If the time of day is after 15:00 the MLM will execute immediately unless the evoke slot contains another time constant (see subsection "use of or"). If the MLM has to be executed the following day, tomorrow can be used as time constant, for example:

```
TOMORROW ATTIME 02:30 AFTER TIME OF penicillin_storage
```

Here, the MLM execution is delayed until 02:30 of the next day. If the execution of the MLM has scheduled for a given day of the week, that day can be also specified within the evoke slot:

```
MONDAY ATTIME 13:00 AFTER TIME OF penicillin_storage
```

The day-of-week is one of the literals Sunday, Monday, Tuesday etc. The MLM execution is delayed until 13:00 of the designated day. If the day of week of "eventtime" is the same as the designated day and eventtime is later than 13:00, the MLM execution is delayed until the following week.

14.3.3.1 *Use of OR*

Time expressions for the delayed trigger can be combined using OR. In this case the whole expression is evaluated to find the next earliest trigger time. For example:

```
MONDAY ATTIME 13:00 OR FRIDAY ATTIME 12:00 AFTER TIME OF penicillin_storage
```

This triggers the MLM on Monday if the event occurs between Friday after 12:00 and Monday before 13:00. If the event occurs outside of this time interval, the MLM is triggered on Friday.

14.3.3.2 *Operation*

The MLM is triggered at the time specified in the delayed trigger statement. This is usually some specified duration after the occurrence of an event. In the special case, that the delay time is given as an absolute point in time, the triggering is delayed to this timestamp, as soon as the event occurs. If the event occurs after this timestamp, the MLM triggers immediately.

14.3.3.3 *Examples*

In the following examples, all variables are event variables:

```
3 days after time of penicillin_storage
1992-01-01T00:00:00 AFTER TIME OF penicillin_storage
TOMORROW ATTIME 02:00 AFTER TIME OF penicillin_storage
```

If time expressions are combined with OR, the MLM will be executed at the next scheduled time.

```
TODAY ATTIME 13:00 OR TOMORROW AT 02:00 AFTER TIME OF penicillin_storage
```

14.3.4   Constant Time Trigger Statement

A **constant time trigger statement** permits the MLM to be triggered at a specific instance in time. It has two forms:

```
<time-expr>
<duration-expr> AFTER <time-expr-simple>
```

<duration-expr> is a duration constant formed by using a number constant (see Section 7.1.7) with a duration operator (see Section 9.10.4).

<time-expr> as defined for the delayed event trigger statement above

<time-expr-simple> is defined as <time-expr> but without <duration-expr>

14.3.4.1 *Operation*

The MLM is triggered at the time specified by the time expression. This is either an absolute point in time, or a relative date (such as tomorrow or simply a duration). A relative date is always evaluated relative to the timepoint when the MLM becomes executable in the system. If a time expression evaluates to a point in time which lies in the past, the MLM is triggered immediately.

For example:

```
                TOMORROW ATTIME 02:30
```

The MLM is triggered the day after it got executable at 02:30.

```
                20 hours
```

The MLM is triggered 20 hours after it got executable.

14.3.4.2   *Examples*

In the following examples, variables are event variables:

```
                1992-01-01T00:00:00
                3 days AFTER 2007-01-01
                TOMORROW ATTIME 02:30
```

If used with time-of-day-constants and more than one time constant is specified in the evoke slot, the MLM will be executed at the next scheduled time.

```
                TODAY ATTIME 13:00 OR TOMORROW AT 02:00
```

14.3.5   Periodic Event Trigger Statement

A **periodic event trigger** statement permits the MLM to be triggered at specified time intervals after an event occurs. The cycles may continue for a specified duration, and they may be terminated by a Boolean condition. It has two forms:

```
        EVERY <duration-expr> FOR <duration-expr> STARTING <delayed-event-trigger>
        EVERY <duration-expr> FOR <duration-expr> STARTING <delayed-event-trigger>
            UNTIL <Boolean-expr>
```

<duration-expr> is a duration constant formed by using a number constant (see Section 7.1.7) with a duration operator (see Section 9.10.4).

<Boolean-expr> is any valid expression. It is usually a Boolean expression that becomes **true** when the MLM triggering should stop.

<delayed-event-trigger> is a **delayed event trigger** as defined above.

Simple trigger statements not using a delayed event trigger also are supported. Example:

```
        EVERY 1 day FOR 14 days STARTING time of event2
```

14.3.5.1   *Operation*

The MLM is first triggered at the time specified after the **starting** word. It is then triggered repeatedly in cycles of length equal to the duration specified after the **every** word. These cycles continue for the duration specified after the **for** word. The **for** duration is inclusive, so **every 1 day for 1 day starting 3 days after time of event1** would trigger the MLM twice: at three days and at four days after the event.

14.3.5.2   *Until*

If there is an **until** clause, then it is evaluated as soon as the MLM is triggered; the clause may contain references to the patient database unrelated to the event. If it is **true** then the MLM exits immediately, and no further triggering occurs. Otherwise, the MLM is executed, and it is triggered again after the **every** duration (assuming the **for** duration has not run out).

14.3.5.3   *Examples*

In the following examples, variables beginning with **event** are event variables:

```
        every 1 day for 14 days starting 1992-01-01T00:00:00 after time of event1
        every 1 day for 14 days starting time of event2
        every 2 hours for 1 day starting today attime 12:00 after time of event3
        every 1 week for 1 month starting 3 days after time of event4 until
            last(serum_potassium) > 5.0
```

14.3.6   Constant Periodic Time Trigger Statement

A **constant periodic time trigger** statement permits the repeatedly execution of a MLM at specific instances of time, independent of events. It has two forms:

```
EVERY <duration-expr> FOR <duration-expr> STARTING <constant-time-trigger>
EVERY <duration-expr> FOR <duration-expr> STARTING <constant-time-trigger>
    UNTIL <Boolean-expr>
```

<duration-expr> as defined for the periodic event trigger statement

<Boolean-expr> as defined for the periodic event trigger statement

<constant-time-trigger> is a **constant time trigger** as defined above.

Consider the following evoke slot:

```
EVERY 1 DAY FOR 5 months STARTING 2008-10-01T06:30;
```

This evoke slot could be used to run an influenza rule every day for the five months of the 2008 flu season.

14.3.6.1   *Operation*

As defined for the **periodic event trigger** statement, but the first execution is determined by a constant time trigger statement.

14.3.6.2   *Until*

As defined for the **periodic event trigger** statement.

14.3.6.3   *Examples*

In the following examples, variables beginning with **event** are event variables:

```
every 1 day for 14 days starting 1992-01-01T00:00:00
every 2 hours for 1 day starting today attime 12:00
every 1 week for 1 month starting 3 days after 1992-01-01T00:00:00 until
    last(serum_potassium) > 5.0
```

14.4 Evoke Slot Usage

The evoke slot usually contains a single statement that specifies when an MLM is triggered. If the evoke slot has more than one statement, then the MLM is evoked whenever any of the criteria in any of the statements occurs.

Annexes
(Mandatory Information)

A1   FORMAL REPRESENTATION

This chapter describes two formal representations of the Arden Syntax. The first is the Backus-Naur Form while the second is the XML representation. Either one or the other can be used to write a normative MLM.

A1.1 Backus-Naur Form

The MLM syntax is defined using Backus-Naur Form (BNF) **(3).** In the interest of readability and computability, the context free grammar is expressed in Backus-Naur Form rather than in the more compact Extended Backus-Naur Form (EBNF) **(3)**. The following definitions hold:

>   <expression> – represents the non-terminal expression
>
>   "IF" – represents the terminal **if**, **iF**, **If**, or **IF**
>
>   ":=" – represents the terminal **:=**
>
>   ::= – is defined as
>
>   /*...*/ – a comment about the grammar
>
> | – or

Terminals are listed in uppercase, but the language is case insensitive outside of character strings. In structured slots, space, carriage return, line feed, horizontal tab, vertical tab, and form feed are considered white space and are ignored. In addition, the terminal **the** is treated as white space (that is, the word **the** is ignored).

With minor modifications, the following grammar can be processed by an LALR(1) parser generator, except where noted by comments against individual rules

```
/****** physical file containing one or more MLMs ******/

/****** file of individual MLMs ******/

A1.2   XML Schema for MLMs

The following sections detail a schema that may be used to represent MLMs in XML. Later versions of Arden Syntax will include alternate, non-textual representations of medical logic modules as part of the normative standard. This informative appendix contains two basic resources. The first is a complete XML schema for Version 2.10 of the Arden Syntax. This schema can be used to express MLMs in XML. The second resource is an XSL Transform which will convert MLMs represented in XML consistent with the published schema into the original ASCII-based representation.

A1.2.1   Graphic Representation of Schema
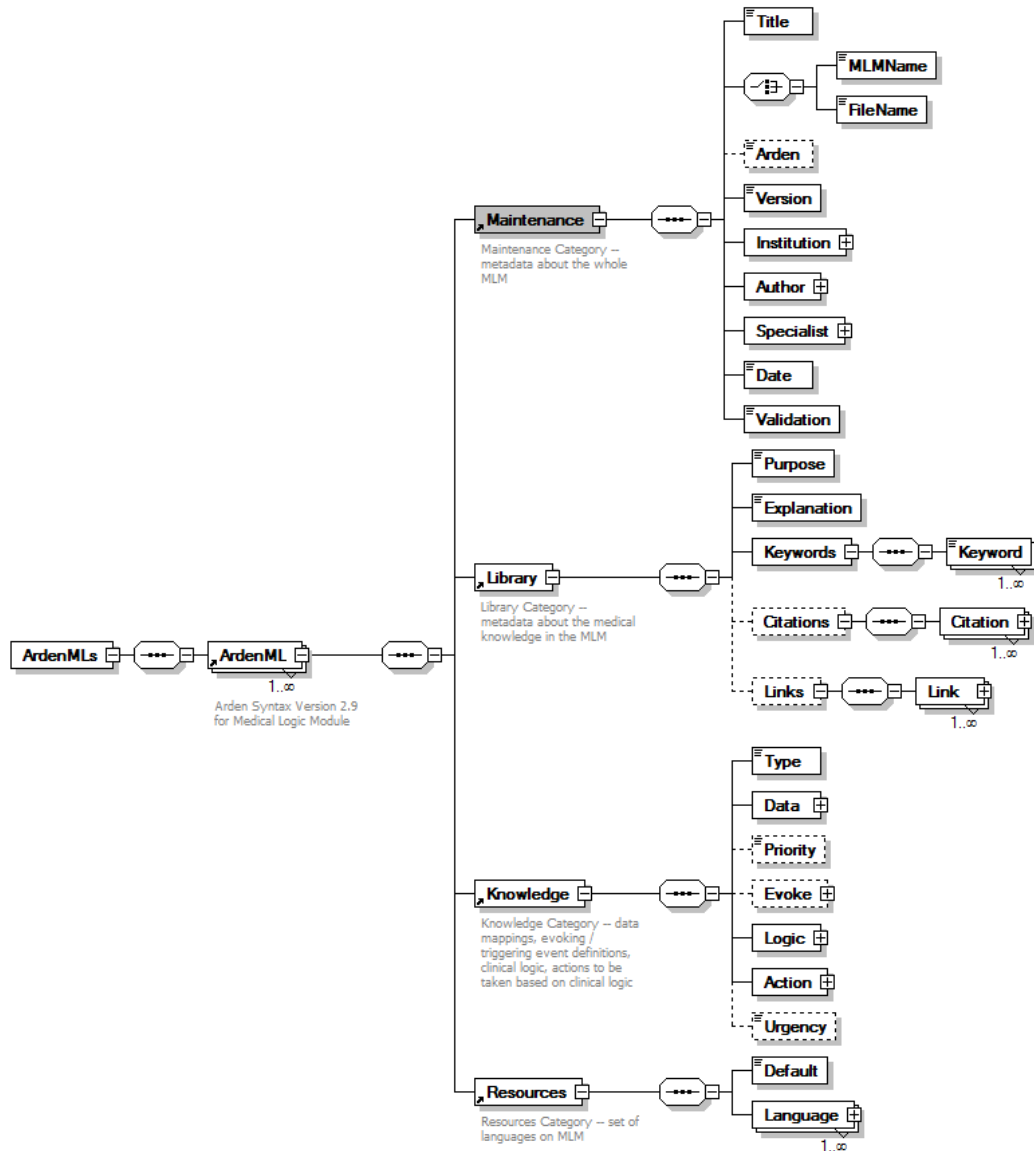

Figure A1.1 Graphic Representation of XML Schema for Arden Syntax MLMs

A1.2.2 Textual Schema

For convenience, the ArdenML schema is broken up into six parts. These are printed below.

A1.2.2.1 File: Arden2_9.xsd.

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema" elementFormDefault="qualified"
attributeFormDefault="unqualified">
    <xs:include schemaLocation="ArdenMaintenance2_9.xsd"/>
    <xs:include schemaLocation="ArdenLibrary2_9.xsd"/>
    <xs:include schemaLocation="ArdenKnowledge2_9.xsd"/>
    <xs:include schemaLocation="ArdenResources2_9.xsd"/>
    <xs:element name="ArdenMLs">
        <xs:complexType>
            <xs:sequence>
                <xs:element ref="ArdenML" maxOccurs="unbounded"/>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
    <xs:element name="ArdenML">
        <xs:annotation>
            <xs:documentation>Arden Syntax Version 2.10 for Medical Logic
Module</xs:documentation>
        </xs:annotation>
        <xs:complexType>
            <xs:sequence>
                <xs:element ref="Maintenance"/>
                <xs:element ref="Library"/>
                <xs:element ref="Knowledge"/>
                <xs:element ref="Resources"/>
                <!-- Removed attribute minOccurs in Arden Syntax version 2.10 -->
            </xs:sequence>
        </xs:complexType>
    </xs:element>
</xs:schema>
```

A1.2.2.2 File: ArdenMaintenance2_9.xsd.

```
<?xml version="1.0" encoding="UTF-8"?>

A1.2.3 XML Transform

An extensible stylesheet language transformations (XSLT) is also available which will convert MLMs expressed in ArdenML into the ASCII form of Arden. This conversion is provided to allow sites familiar with the standard, textual version of Arden MLMs to easily review and incorporate MLMs expressed in XML.

A4   OPERATOR PRECEDENCE AND ASSOCIATIVITY

A4.1

The operators for the structured slots are shown here grouped by precedence. Groups are separated by horizontal lines. Within groups, operators have equal precedence. Groups are arranged from lowest to highest precedence.

A4.2

Synonyms are listed on the same line, separated by º. The symbol [of] means that the word **of** is optional, and does not affect the logic of the operator. The symbol [in] means that the work **in** is optional, and does not affect the logic of the operator.

A4.3

The position of the arguments relative to the operator is indicated by the ellipsis .... The operator's associativity is shown in italics after each operator. Some operators have both a unary form (one argument) and a binary form (two arguments); each form is listed separately.

A5   FORMAT SPECIFICATION (SEE 9.8.2)

A5.1   The following is a complete description of supported types within the format specification:

type   Required character that determines whether the associated argument is interpreted as a character, a string, or a number.

Table A5-1

Character	Type	Output Format
c	number	The number is assumed to represent a character code to be output as a character.
C	number	The number is assumed to represent a character code to be output as a character.
D	number	Signed decimal integer.
I	number	Signed decimal integer.
O	number	Unsigned octal integer.
U	number	Unsigned decimal integer.
x	number	Unsigned hexadecimal integer, using "abcdef."
X	number	Unsigned hexadecimal integer, using "ABCDEF."
e	number	Signed value having the form [–]d.dddd e [sign]ddd where d is a single decimal digit, dddd is one or more decimal digits, ddd is exactly three decimal digits, and sign is + or –.
E	number	Identical to the e format, except that E, rather than e, introduces the exponent.
F	double	Signed value having the form [–]dddd.dddd, where dddd is one or more decimal digits. The number of digits before the decimal point depends on the magnitude of the number, and the number of digits after the decimal point depends on the requested precision.
g	double	Signed value printed in f or e format, whichever is more compact for the given value and precision. The e format is used only when the exponent of the value is less than –4 or greater than or equal to the precision argument. Trailing zeros are truncated, and the decimal point appears only if one or more digits follow it.
G	double	Identical to the g format, except that E, rather than e, introduces the exponent (where appropriate).
N	Not supported.	Not supported.
P	Not supported.	Not supported.
S	string	Specifies a character. Characters are printed until the precision value is reached.
T	time	A time is printed based on the user's environment settings and the precision value.

A5.2   The optional fields, which appear before the type character, control other aspects of the formatting, as follows:

flags   Optional character or characters that control justification of output and printing of signs, blanks, decimal points, and octal and hexadecimal prefixes. More than one flag can appear in a format specification.

Table A5-2

Flag	Meaning	Default
–	Left align the result within the given field width.	Right align.
+	Prefix the output value with a sign (+ or –) if the output value is of a signed type.	Sign appears only for negative signed values (–).
0	If width is prefixed with 0, zeros are added until the minimum width is reached. If 0 and – appear, the 0 is ignored. If 0 is specified with an integer format (I, u, x, X, o, d) the 0 is ignored.	No padding.
Space	Prefix the output value with a space if the output value is signed and positive; the space is ignored if both the space and + flags appear.	No space appears.
#	When used with the o, x, or X format, the # flag prefixes any nonzero output value with 0, 0x, or 0X, respectively.	No blank appears.
#	When used with the e, E, or f format, the # flag forces the output value to contain a decimal point in all cases.	Decimal point appears only if digits follow it.
	When used with the g or G format, the # flag forces the output value to contain a decimal point in all cases and prevents the truncation of trailing zeros.	Decimal point appears only if digits follow it. Trailing zeros are truncated.
#	Ignored when used with c, d, i, u, or s.	

The second optional field of the format specification is the width specification. The width argument is a nonnegative decimal integer controlling the minimum number of characters printed. If the number of characters in the output value is less than the specified width, blanks are added to the left or the right of the values – depending on whether the – flag (for left alignment) is specified – until the minimum width is reached. If width is prefixed with 0, zeros are added until the minimum width is reached (not useful for left-aligned numbers).

The width specification never causes a value to be truncated. If the number of characters in the output value is greater than the specified width, or if width is not given, all characters of the value are printed (subject to the precision specification).

If the width specification is an asterisk (*), an integer argument from the argument list supplies the value. The width argument must precede the value being formatted in the argument list. A nonexistent or small field width does not cause the truncation of a field; if the result of a conversion is wider than the field width, the field expands to contain the conversion result.

Width   Optional number that specifies the minimum number of characters output.

Precision   Optional number that specifies the maximum number of characters printed for all or part of the output field, or the minimum number of digits printed for integer values.

Print date: 10/4/2023

Table A5-3

Type	Meaning	Default
c, C	The precision has no effect.	Character is printed.
D, i, u, o, x, X	The precision specifies the minimum number of digits to be printed. If the number of digits in the argument is less than precision, the output value is padded on the left with zeros. The value is not truncated when the number of digits exceeds precision.	Default precision is 1.
E, E	The precision specifies the number of digits to be printed after the decimal point. The last printed digit is rounded.	Default precision is 6; if precision is 0, or the period (.) appears without a number following it, no decimal point is printed.
F	The precision value specifies the number of digits after the decimal point. If a decimal point appears, at least one digit appears before it. The value is rounded to the appropriate number of digits.	Default precision is 6; if precision is 0, or if the period (.) appears without a number following it, no decimal point is printed.
G, G	The precision specifies the maximum number of significant digits printed. The last printed digit is rounded.	Six significant digits are printed, with any trailing zeros truncated.
S	The precision specifies the maximum number of characters to be printed. Characters in excess of precision are not printed.	Characters are printed until a null character is encountered.
T	The precision specifies how many of the date and time fields are printed. The order and format of the fields are implementation specific. Non-printed fields are truncated (rounded down). 0: Year only 1: Year, Month 2: Date (Year, Month, Day) 3: Date, hour 4: Date, hour, minute 5: Date, hour, minute, second	All fields are printed.

A6   OBJECTS IN ARDEN SYNTAX

A6.1 Rationale

Objects were introduced in Arden 2.5. These have been added as an enhancement to the Arden Syntax to address user and vendor concerns about Arden limitations, and to dramatically increase the capabilities of the syntax. This is an evolutionary step toward full support for receiving data in HL7 V3 messages.

Arden Syntax was originally designed to be very simple, and was limited to a single method of combining data: the ordered list. To simplify list handling, and avoid complexities of things like lists containing lists, the syntax specifies that lists contain only individual items. This has some significant limitations.

Repository data, which typically is represented logically as tables, is returned by the READ statement as a set of columnar lists which are then assigned to separately named variables. After a READ, it can be difficult to maintain the links between values which are naturally associated with each other. For example, the last item of **firstnames** and the last item of **lastnames** may correspond, but what happens if a new item is added to one of the lists, or one of the lists is reordered? The correspondence is lost.

As MLMs evolve, they typically gain features, size and complexity via successive refinement. Declaring new variables for every temporary computation in an MLM clutters the MLM name space with names which often have little meaning. MLM authors tend to start using lists as ad-hoc data structures, where the first, second etc. items, rather than representing multiple instances of a piece of data, instead represent several different types of data which are united by a common relationship. In most computer languages these would be stored in a specialized data structure, with a declared name for each item. Items in a list can only be referred to via their index (a number) which is not easy to read or understand.

Structured data is actually a simplifying concept. Introducing structured data types, while allowing complex structures, tends to make any given usage simpler because of the ability to declare names and relationships. The addition of Objects to the 2.5 standard acknowledges this, and this enhances the Arden Syntax in a number of ways:

- Database queries can be returned as a list of rows, each of which contains named attributes and values.

- Object domain models, such as the HL7 models, may be adapted to Arden and referenced in a natural way as objects by MLMs.

- Complex data structures, as needed, may be created and manipulated easily. Object attributes can contain lists or other object instances, allowing arbitrary depth.

A design goal, in incorporating objects into Arden, was full backward compatibility, and to introduce as few reserved words and as little new syntax as possible. New reserved words cause a compatibility problem because existing MLMs may use those reserved words as variable names. We have only added two more reserved words. Syntax changes are summarized:

- New reserved words: **new**, **object**

- New syntax (special characters): dot (**.**) for object reference, square braces (**[]**) to denote attributes in an object declaration statement.

- New operators: **dot** (**.**) operator, **is object**, **is not object**, **read as**

A6.2 Object Details

The term **object** is used in the domain model sense, rather than as a programming language artifact. In Arden an object is a structured data type, which has a name, and an ordered collection of attributes. Each of these attributes may refer to any valid Arden data item, or be null. Each of these data items may have a primary time associated with it, but the object itself does not have a primary time independent of its attributes. For convenience, if all attributes of an object share a common primary time, the **time of** operator will return that time when applied to the object.

Revision date: 4/25/2023
Print date: 10/4/2023

A6.3 Object Identity

Objects in Arden have an identity, which is preserved when assigned or used as an argument to an operator, added to lists or extracted from lists. Objects only are created when the **new** statement is called (from either the data slot or logic slot) or via the **read as** statement in the data slot. An MLM may also reference objects which are passed as arguments or returned from calls to other MLMs. Object identity is not maintained when passed as an argument to an MLM call or a foreign interface, or returned from MLMs. That is, an object is always copied when passed to or returned from an MLM (objects are passed by value to other MLMs, not by reference).

Objects allow an MLM to create structured data, store it in a list, modify it while it still exists in the list, and later reference it as part of the list. While this may sound complicated, it is an important feature. It allows Arden syntax to remain fairly simple while still allowing the easy reference and manipulation of query results.

```
// Assume a list of order objects, with attributes including status and
// message.
// This MLM wants to set the message based on the status.
For order_obj in order_obj_list do
   if order_obj.status = "Cancel" then
      order_obj.msg := "This order has been cancelled.";
   elseif order_obj.status = "Modify" then
      order_obj.msg := "This order has been modified.";
   elseif order_obj.status = "Suspend" then
      order_obj.msg := "This order has been suspended.";
   endif;
enddo;
```

This code only works correctly because of object identity. The order_obj in the loop corresponds to the order referenced in the list of order objects. Without object identity it would not be possible to do this type of manipulation on lists of items.

At this time it is not possible to determine in Arden if two variables refer to the same object. That is, the equality operator is not defined for objects, and there is no substitute method defined. This may be a something to add in a future version.

A6.4 Objects In Expressions

If an object is passed to a standard Arden operator (equality operator, addition, etc) which does not explicitly define behavior with objects, the result of the operation will be null. To effectively use an object as an argument to these standard operators, you must reference a particular field within the object (using the **dot** operator) so that the resulting type is not an object.

A6.5 Creating Objects

The **new** statement can be used to create object instances, with all attributes initialized to null. Using attribute assignment statements (Section 10.2.1.1) it is possible to set these fields explicitly after creating the object. Sometimes however it is preferable to create an MLM which acts as a constructor, to create an object and initialize attributes to the desired default values. Any time one of these objects needs to be created, that MLM can be called. Here is an example of using an MLM as a constructor:

```
Create_field_mlm := MLM 'create_form_field';
Form_field := Call Create_field_mlm with name, value, status;

/* MLM 'create_form_field' segment */
Data:
   form_field_type :=
      Object [name, value, status];
   field := new form_field_type;
   field.name := argument1;
   field.value := argument2;
   field.status := argument3;;
```

```
Evoke: /* called directly */ ;;
Logic: conclude true;;
Action: return field;;
```

Appendices

(Nonmandatory Information)

X1 LANGUAGE AND COUNTRY CODES FOR HL7 INTERNATIONAL AFFILIATE COUNTRIES

X1.1 Introduction

This appendix lists language and country codes as defined by ISO 639.1 and ISO 3166 for countries with HL7 Affiliates. Languages and country codes are arranged in alphabetic order by their English-language name. For additional language and country codes consult the appropriate ISO language / country registrars via ISO (www.iso.ch).

X1.2 Language Codes

Language	Code	Language	Code
Assamese	as	Kannada	kn
Basque	eu	Kashmiri	ks
Bengali	bn	Korean	ko
Catalan; Valencian	ca	Kurdish	ku
Chinese	zh	Malayalam	ml

X2   SAMPLE MLMS

The following are sample MLMs to be used only to demonstrate the syntax. They have not been tested, and they have not been used in clinical care.

X2.1   Data Interpretation MLM

```
maintenance:
    title: Fractional excretion of sodium;;
    mlmname: fractional_na;;
    arden: Version 2;;
    version: 1.00;;
    institution: Columbia-Presbyterian Medical Center;;
    author: George Hripcsak, M.D.
                (hripcsak@cucis.cis.columbia.edu);;
    specialist: ;;
    date: 1991-03-13;;
    validation: testing;;
library:
    purpose:
            Calculate the fractional excretion of sodium whenever urine
            electrolytes are stored. (This MLM demonstrates data
            interpretation across independent laboratory results.);;
    explanation:
            The fractional excretion of sodium is calculated from the urine
            sodium and creatinine and the most recent serum sodium and
            creatinine (where they occurred within the past 24 hours). A
            value less than 1.0 % is considered low.;;
    keywords: fractional excretion; serum sodium; azotemia;;
    citations:

```

X2.2   Research Study Screening MLM

```
maintenance:
    title: Screen for hypercalcemia for Dr. B.'s study;;
    mlmname: hypercalcemia_for_b;;
    arden: Version 2;;
    version: 2.02;;
    institution: Columbia-Presbyterian Medical Center;;
    author: George Hripcsak, M.D.;;
    specialist: ;;
    date: 1990-12-04;;
    validation: research;;
library:
    purpose:
            Screen for hypercalcemia for Dr. B.'s study. (This MLM demonstrates
            screening patients for clinical trials.);;
    explanation:
            The storage of a serum calcium value evokes this MLM. If a serum
            albumin is available from the same blood sample as the calcium,
            then the corrected calcium is calculated, and patients with actual
            or corrected calcium greater than or equal 11.5 are accepted; if
            such a serum albumin is not available, then patients with actual
            calcium greater than or equal 11.0 are accepted. Patients with
            serum creatinine greater than 6.0 are excluded from the study.;;

X2.4 Management Suggestion MLM

```
maintenance:
    title: Dosing for gentamicin in renal failure;;
    mlmname: gentamicin_dosing;;
    arden: Version 2.1;;
    version: 1.00;;
    institution: Columbia-Presbyterian Medical Center;;
    author: George Hripcsak, M.D.;;
    specialist: ;;
    date: 1991-03-18;;
    validation: testing;;
library:
    purpose:
            Suggest an appropriate gentamicin dose in the setting of renal
            insufficiency. (This MLM demonstrates a management suggestion.);;
    explanation:
            Patients with renal insufficiency require the same loading dose of
            gentamicin as those with normal renal function, but they require a
            reduced daily dose. The creatinine clearance is calculated by serum
            creatinine, age, and weight. If it is less than 30 ml/min, then an
            appropriate dose is calculated based on the clearance. If the
            ordered dose differs from the calculated dose by more than 20 %,
            then an alert is generated.;;

X3   SUMMARY OF CHANGES

X3.1   Summary of Changes from the 1992 Standard (Version 1) to Version 2

- Clarification of many details of operator definitions.
- **Arden syntax version** slot required. (6.1.3)
- Citations must be numbered, and can be classified as supporting or refuting. (6.2.4)
- Specification of Links slot (6.2.5)
- Times can be constructed from durations via + operator (7.1.12)
- **Triggertime** is the time the MLM was triggered (8.4.5)
- Query retrieval order is not necessarily by primary time (8.9.2)
- **Interface** statement for using external functions (11.2.16)
- Single-line comments may be introduced with "//". (7.1.19)
- The **filename** slot has been renamed to **mlmname**. (6.1.2)
- Some new operators have been introduced:
    - **sort** (9.2.4)
    - **reverse** (9.12.21)
    - **format** (9.8.2)
    - **earliest**, **latest** (9.12.17, 9.12.16)
    - **floor, ceiling, truncate, round** (9.16.11, 9.16.12, 9.16.13, 9.16.14)
    - **index** (...[...]) (9.12.18)
    - **year, month, day, hour, minute, second** field extraction (9.10.7, 9.10.8, 9.10.9, 9.10.10, 9.10.11, 9.10.12)
    - **seqto** (9.12.20)
    - **string**, **extract characters** (9.8.3, 9.12.19)
- Operators which select from lists may be annotated to return indexes instead of the elements. (9.12.18)
- **As number** operator which converts strings and Booleans to numbers. (9.20.1)
- Some restrictions have been removed (e.g., double semi-colon inside strings).
- The **call** expression and statement can now pass multiple arguments; arguments may also be passed from an action slot. (10.2.5, 11.2.5, 13.2.2, 13.2.5)
- Looping constructs have been added: for loop, while loop. (10.2.5.10, 10.2.6.1)
- The **continue** statement may have an **unless** added to it (this a readability aid).
- A new form of conditional execution, by allowing **unless** in a **conclude** statement.
- The **read ... where ...** no longer requires parentheses.
- A read query may specify a sort order (different from the default of chronological by primary time).

X3.2   Summary of Changes from Version 2 to Version 2.1

- A structured message for the **write** statement, represented as a Document Type Definition to be encoded in the Extensible Markup Language (XML), has been included. (A1.2.2.4)

- The **in** operator is now a synonym for **is in**; similarly, **not in** is synonymous with **is not in**. (9.6.23)

- **Occur/occurs/occurred at** is now synonymous with **occur/occurs/occurred equal**. (9.7.11)

- The syntax **from <time>** is now synonymous with **after <time>**. (9.10.4)

- A period punctuation mark (".") now is permissible in the **Mlmname** slot. (6.1.2)

- New reserved word **currenttime** returns the system time at any point during an MLM's execution. (8.4.6)

- Six new string-handling operators are now available. These include **length** (9.8.5), **uppercase** (9.8.6), **lowercase** (9.8.7), **trim** (9.8.8), **find…in string** (9.8.9), and **substring…characters from** (9.8.10).

- The **where trigger** statement has been removed.

- Added new code for Arden Syntax version slot—Version 2.1—to distinguish Version 2 and Version 2.1 compliant MLMs.

Print date: 10/4/2023

X3.3   Summary of Changes from Version 2.1 to Version 2.5

The following relate to new Object capabilities:
Added new sections:
- 10.2.7, **New** statement.
- 11.2.1.9, **Read As** statement.
- 11.2.5.2 **Message As** statement
- 11.2.5.6 **Destination As** statement
- 11.2.13, **Object** statement.
- 10.2.1.1, **Attribute assignment** statement.
- 9.18, **Dot** notation (attribute reference)
- 9.19, **Clone** operator (attribute reference)
- 8.10, **Object** data type
- Annex A6, Objects in Arden: rationale, details, etc.

Section A4.3, new operators is object, is not object, is <object-name>, is not <object-name> were added.

The following updates relate to new recommendations for formatting structured citations and links
- 6.2.4, **Citations** slot now recommends ANSI/NISO OpenURL format for structured citations
- 6.2.5, **Links** slot now recommends ANSI/NISO OpenURL format for structured links
- Annex A1, XML schema for MLMs replaces DTD

The following updates relate to new recommendations for representing MLMs using XML
- Appendix X1, XML schema for structured write replaces DTD for structured write
- Appendix X2, XML schema for MLMs added

Annex A1 Backus-Naur Form updated to include new operators, statements, and correct errors from previous versions
Updated B/N forms for:
- <data_assign_phrase>
- <expr_factor>
- <logic_assignment>   (fixed a problem in 2.1 B/N form relating to calling MLMs that return multiple values)
- <identifier_becomes>
- <unary_comp_op>
- <data_assignment>
- <expr_function>
- <of_noread_func_op>

These B/N Forms were added:

- <object_definition>

- <object_attribute_list>

- <new_object_phrase>

- <identifier_or_object_ref>

- <expr_attribute_from>

- **Annex A2 Reserved Words updated to include new operators and statements**

- **Annex A4 Operator Precedence and Associativity updated to include new operators**

X3.4   Summary of Changes from Version 2.5 to 2.6

- **5.1 Character set allows UNICODE encoding within certain limitations**

- **6.2.5   Changes to structured version of links slot.**

- **6.4 Resource category defines text resources for specific languages**

- **7.1.11   Time of day constants**

- **8.11   Time-of-day data type**

- **8.12   Day-of-week data type**

- **9.1.5   Time of day handling**

- **9.6.21   Is [not] time of day**

- **9.10.5   Time of day operator**

- **9.10.6   Day of week operator**

- **9.8.11   Localized operator (unary)**

- **9.8.12   Localized operator (binary)**

- **9.17.3   At**

- **11.2.15 Extension of include statement to include resources**

- **X3 Selected language and country codes for use with resource category slots.**

This version features new data types and operators to represent time-of-day and day-of-week. In addition, new capabilities have been added to let an MLM report messages in a variety of languages. The modifications include:

X3.5   Summary of Changes from Version 2.6 to 2.7

- 9.17.3   **AT** (time) changed to **ATTIME** to remove need for precedence rules to proper parse use of

    AT (time) in write statement with destination.

- 10.2.1.2   Enhanced Assignment Statement   changed to support directly assigning to nested attributes

    of objects and specific elements in a list

- 10.2.4.10   Enhanced Assignment in Call Statement

- 10.2.7.1   New Statement with Named Initializer (objects)

- Evoke slot chapter reorganized and rewritten

- Changes to BNF to reflect updates to text of standard and fix typographical errors

Revision date: 4/25/2023   Print date: 10/4/2023

X3.6   Summary of Editorial Corrections of ANSI/HL7 Arden V2.7-2008 December 10, 2008

- TOC Updated numbering of sections 11.2.10 to 11.2.18 in the table of contents

- 9.1.3 Added "*Each operator must apply the here described list handling first (if applicable) before the specific list handling as described in the respective operator description is applied.*" to make the correct application of list handling clearer.

- 9.1.3.4 Removed **… matches pattern …** because this does not belong to this chapter.

- 9.1.3.4 added missing **… from …** operator

- 9.3.1 Correction of first example since the stated operator **… is within … after …** does not exist, **… is within … following …** must be used.

- 9.4.1 Type constraint updated because **… or …** is also applicable to lists.

- 9.7 Several "occured" changed to "occurred".

- 9.8.1 Corrected **%z** to **%s** because there is no such operator **%z**.

- 9.8.4 2nd type constraint removed. <k:list of strings> means a list with k elements of "list of strings", which is a list of lists and not allowed in Arden Syntax.

- 9.9.7 Type constraint corrected to ensure that the right side of the **… ** …** operator is not a list.

- 9.12.19 Updated the type constraint for **extract characters** operator to ensure that the list of arguments is of type string.

- 10.2.1.2 Operator corrected (**element** instead of **index**), corrected examples ("msg" instead of "message", "message" not allowed as variable name)

- 10.2.7 Definition of non-terminal **<object-identifier>** added.

- 11.2.5 Removed "*[...] If the MLM is evoked instead of called, all the arguments are treated as null. [...]*" since this sentence is in contradiction with Section 10.2.4.6.

- 11.2.8 to 11.2.18 Updated numbering of sections.

- A1 BNF expression for `<read_where>` updated with missing "<" and ">".

- A1 BNF expression for `<evoke_statement>` updated with the missing non-terminal `<delayed_evoke>`

- A1 BNF expression for `<delayed_evoke>` updated with the missing quotation marks.

- A1 BNF expression for `<relative_evoke_time_expr>` updated, since this non-terminal was still using "AT" instead of "ATTIME"

- A2 **arccos** instead of **arcos**

- A4 Operators added to precedence groups: 9.16.10, 9.16.14

- A4 **arccos** instead of **arcos**

- A5.1 Some letters must be lowercase instead of using them in uppercase twice.

X3.7   Summary of Changes from Version 2.7 with Editorial Corrections to 2.8

- 3.2.1, Removed the "a point in absolute time" term

- 6.1.2, Added the **minus** sign, since the BNF (non-terminal `<mlmname_text_rest>`) allows this sign inside of an MLM name

- 6.1.7, Changed slot type to "textual list" since the informal description claims the same format as the author slot

- 6.1.8, Added short term, which makes clear that only the complete representation (given in the **ISO**) is allowed

- 8.1, Added a sentence to make clear that null may have a primary time

- 8.4.1, Changed the granularity of time from infinitesimal to implementation specific (beyond milliseconds)

- 9.1.2.2, Additional data type "**times**" introduced, which subsumes **time** and **time-of-day**

- 9.1.2.2, Added "**time-of-day**" within the types: **any-type**, **non-null**, and **ordered**

- 9.1.3.1, Added the operators "**… As Number**", "**… As String**", and "**… As Time**" to the general list handling

- 9.1.3.4, Added the operators "**Replace Year Of … With**", "**Replace Month Of … With**", "**Replace Day Of … With**", "**Replace Hour Of … With**", "**Replace Minute Of … With**", and "**Replace Second Of … With**" to the general list handling

- 9.1.3.6, Added the operators "**Index Of … From …**", "**Add … To …**", "**At Least … From …**", and "**At Most … From …**" to the general list handling

- 9.1.3.7, Added the "**Remove … From …**" operator to the general list handling

- 9.2.4, Added the "**Using …**" modifier as extension to the **sort** operator. This modifier will allow to sort lists by any complex calculation

- 9.2.5, Added new operator "**Add … To … [At …]**" for simple list manipulation by insertion of elements at arbitrary positions

- 9.2.6, Added new operator "**Remove … From …**" for simple removing arbitrary elements from a list

- 9.6.7, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.6.8, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.6.9, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.6.10, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.6.12, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.6.13, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.6.14, Added 2 sentences to make the null handling of the "**… Is [Not] In …**" operator clearer

- 9.7.2, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.7.3, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.7.4, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.7.5, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.7.6, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.7.9, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.7.10, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.7.11, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.8.13, Added new operator "**As String**" to convert any data into a string

- 9.9.1, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.9.3, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.10.1, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.10.2, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.10.4, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.10.7, Moved operator "**Extract Year**" from section 9.11.2

- 9.10.8, Moved operator "**Extract Month**" from section 9.11.4

- 9.10.9, Moved operator "**Extract Day**" from section 9.11.7

- 9.10.10, Moved operator "**Extract Hour**" from section 9.11.9

- 9.10.10, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.10.11, Moved operator "**Extract Minute**" from section 9.11.11

- 9.10.11, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.10.12, Moved operator "**Extract Second**" from section 9.11.13

- 9.10.12, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.10.13, Added new operator "**Replace Year [Of] … With**" to set the year part of a given date

- 9.10.14, Added new operator "**Replace Month [Of] … With**" to set the month part of a given date

- 9.10.15, Added new operator "**Replace Day [Of] … With**" to set the day part of a given date

- 9.10.16, Added new operator "**Replace Hour [Of] … With**" to set the hour part of a given date

- 9.10.17, Added new operator "**Replace Minute [Of] … With**" to set the minute part of a given date

- 9.10.18, Added new operator "**Replace Second [Of] … With**" to set the second part of a given date

- 9.12.3, Added a sentence to make clear what the **exists** operator does if the parameter is a single item

- 9.12.4, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.12.5, Changed the operator type constraint from `<n:time>` to `<n:times>` to describe that **time-of-day** values are also allowed

- 9.12.9, Added the ability to use the "**using**" modifier, too

- 9.12.10, Added the ability to use the "**using**" modifier, too

- 9.12.13, Added the optional keyword "**IsTrue**"

- 9.12.14, Added the optional keyword "**AreTrue**"

- 9.12.15, Added the optional keyword "**IsTrue**"

- 9.12.16, Added a sentence to make clear what happens if there is more than one element with the latest primary time

- 9.12.16, Added the ability to use the "**using**" modifier, too

- 9.12.17, Added a sentence to make clear what happens if there is more than one element with the earliest primary time

- 9.12.17, Added the ability to use the "**using**" modifier, too

- 9.12.20, Corrected an example (added brackets) since **seqto** operator has higher precedence than unary minus

- 9.13.2, Corrected the operators type constraint, since the formal description only allows single times as first parameter

- 9.13.4, Added new operator "**Index Of … From …**" to find the index of a specific list element

- 9.13.5, Added the "**At Least … [IsTrue|AreTrue] From …**" operator to determine if a list contains at least N elements which are true

- 9.13.6, Added the "**At Most … [IsTrue|AreTrue] From …**" operator to determine if a list contains at most N elements which are true

- 9.14.2, Added the ability to use the "**using**" modifier, too

- 9.14.3, Added the ability to use the "**using**" modifier, too

- 9.14.6, Added new operator "**Sublist … Elements [Starting at …] From …**" to extract sub-lists from given data lists

- 9.14.7, Adjusted the second type constraint such that the operator can handle lists of **time-of-day** values and added an example

- 9.14.8, Adjusted the second type constraint such that the operator can handle lists of **time-of-day** values and added an example

- 9.14.11, Added the ability to use the "**using**" modifier, too

- 9.14.12, Added the ability to use the "**using**" modifier, too

- 9.16.10, Corrected the first two examples (added brackets) since **int** operator has higher precedence than unary minus

- 9.16.12, Corrected the first two examples (added brackets) since **ceiling** operator has higher precedence than unary minus

- 9.16.13, Corrected the first two examples (added brackets) since **truncate** operator has higher precedence than unary minus

- 9.16.14, Corrected the last three examples (added brackets) since **round** operator has higher precedence than unary minus

- 9.17.1, Added a sentence to make clear what happens if a non-time value is used for the assignment

- 9.17.4, Added new operator "**As Time**" to convert a string into a time data type

- 9.18.3, Changed the operators type constraint such that only one object can be passed

- 10.2.1, Changed the description such that it will be clear that a re-assignment is allowed nowhere outside of the data slot

- 10.2.3, Added the "**Switch-Case**" statement for simple distinction of different states of a variable

- 10.2.3.1, Added a section to describe the "**Simple Switch-Case**" statement

- 10.2.3.2, Added a section to describe the "**Switch-Case-Default**" statement

- 10.2.6.1, Added the possibility to use the terminal "**BreakLoop**" for aborting a while loop

- 10.2.7.1, Added the possibility to use the terminal "**BreakLoop**" for aborting a for loop

- 11.2.3.1, Added a sentence to describe the default Boolean value of a variable that represents an event
- 11.2.12, Added the "**Switch-Case**" statement to the data slot, too
- 11.2.14, Added a reference to the **breakloop** statement
- 11.2.15, Added a reference to the **breakloop** statement
- 11.2.19, Added MLM, event, and interface variable to the listing, since section 10.2.5.2 claims that they are also included
- 12.2.4, Added the "**Switch-Case**" statement to the action slot, too
- 12.2.6, Added a reference to the **breakloop** statement
- 12.2.7, Added a reference to the **breakloop** statement
- A1 BNF, Added version 2.7 and 2.8 to the non-terminal and `<arden_version>`
- A1 BNF, added multiple non-terminals (`<action_switch>`, `<logic_switch>`, and `<data_switch>`) and added them to the general statements for the **data**, **action**, and **logic** slot to allow switch statements in all of these slots
- A1 BNF, Added the terminal "**BREAKLOOP**" to the non-terminals `<logic_statement>`, `<data_statement>`, and `<action_statement>`
- A1 BNF, Adjusted non-terminals `<identifier_becomes>` and `<identifier_or_object_ref>` to allow the enhanced assignment statements described in 10.2.1.2
- A1 BNF, Added **using** modifier to the non-terminal `<expr_function>` and to the non-terminal `<expr_sort>`
- A1 BNF, Added the new operator "**Add … To …**" to the non-terminal `<expr_sort>` and inserted a new non-terminal `<expr_add_list>`
- A1 BNF, Added the new operator "**Remove … From …**" as non-terminal `<expr_remove_list>`
- A1 BNF, Added an additional "**… Formatted With …**" line to the non-terminal `<expr_string>` to allow complex format strings
- A1 BNF, Removed the terminals "**Uppercase**" and "**Lowercase**" from the non-terminal `<of_noread_func_op>` and added them to the non-terminal `<expr_string>` as non-terminal `<case_option>`
- A1 BNF, Added non-terminal `<expr_attime>` to prevent infinite loops while parsing **attime** statements
- A1 BNF, Added alternative non-terminal to the BNF-expression `<expr_duration>`
- A1 BNF, Added the new operators "**Replace <Timepart> Of … With …**" to the non-terminal `<expr_funtion>`
- A1 BNF, Added the **at least** and the **at most** operator as non-terminal `<at_least_most_op>` to the non-terminal `<expr_function>`
- A1 BNF, Added the "**Index Of … from …** " operator to the non-terminal `<expr_function>`
- A1 BNF, Added the **sublist** operator to the non-terminal `<expr_function>` by adding the non-terminal `<expr_sublist_from>`
- A1 BNF, Added the optional keywords "**IsTrue**" and "**AreTrue**" to the operators **no**, **any** and **all** in the non-terminal `<of_noread_func_op>`
- A1 BNF, Added the new operator "**… As Time**" to the non-terminal `<as_func_op>`
- A1 BNF, Added the new operator "**… As String**" to the non-terminal `<as_func_op>`
- A1 BNF, Added an additional non-terminal `<timepart>`
- A1 BNF, Changed the non-terminal `<delayed_evoke>` to fit the informal description which does allow only simple duration statements on the left side of constant time trigger statements
- A1, BNF, Change description of the `<plainstring>` non-terminal since both, the regular expression and the informal description (7.1.6) does allow ";;" in a string
- A1 BNF, Added non-terminal `<seconds>` and adjusted the `<time_of_day>` non-terminal definition

- A2, Added the following words to the list of reserved words: **add**, **aretrue, breakloop, case**, **elements**, **istrue, least**, **most**, **remove**, **replace, sublist**, **switch**, **using**

- A4, Added the **element** operator

- A4, Added the unary **comma** operator to the list of precedence

- A4, Added the "**Add … To … [At …]**" operator

- A4, Added the "**Remove … From …**" operator

- A4, Removed binary "**… Round …**" operator, which is not defined in the specification

- A4, Added the "**Sublist … elements [Starting At …] From …**" operator in its two occurrences

- A4, Added the "**Index Of … Within …**" operator

- A4, Added the "**At Least …**" operator

- A4, Added the "**At Most …**" operator

- A4, Added the "**Replace <timepart> Of … With …**" operators

- A4, Added "**… Seqto …**" operator as new group at the end of the list

- A4, Added new precedence group for "**… As Number**", "**… As Time**", and "**… As String**"

- A4, Split some precedence groups since operators with different associativity should not be in the same precedence group

- A4, Added the operators extended by the **using** modifier

X3.8   Summary of Changes from Version 2.8 to 2.9

- 6.4, changed **resources** category definition from optional to required, stating that in former versions this category is optional and a default value is used
- 8.13, new data type **Truth Value** which is a generalization of Boolean
- 8.14, new **fuzzy data type** section which contains a set of data types to express fuzzy sets
- 8.15, added **applicability**, similar to "primary time" a new subcomponent is added which allows to express the applicability of a value
- 9.1.2.2, changed some **type categories** and added some new type categories to allow to use them in the operator signatures
- 9.1.3, added the new operators to **list handling** explanation
- 9.1.6, added **general applicability handling** (similar to primary time handling)
- 9.2.4, **sort** operator adjusted to be able to sort a list by the **applicability** of the values
- 9.4.1, adjusted the **or** operator to handle truth values
- 9.4.2, adjusted the **and** operator to handle truth values
- 9.4.3, adjusted the **not** operator to handle truth values
- 9.5.4, adjusted the **<=** operator to handle a crisp and a fuzzy data type
- 9.5.5, adjusted the **>=** operator to handle a crisp and a fuzzy data type
- 9.6.14, the **is [not] in** operator is now able to handle a crisp and a fuzzy data type to find the mapping of the crisp value to the given fuzzy set
- 9.6.27, new operator **is[not] fuzzy** to check a value if it is fuzzy or not
- 9.6.28, new operator **is[not] crisp** to check a value if it is crisp or not
- 9.13.5, adjusted the **at least** operator to handle truth values in a list
- 9.13.6, adjusted the **at most** operator to handle truth values in a list
- 9.19, new section **fuzzy operators** to store all operators on fuzzy sets
- 9.19.1, added new operator **fuzzy set ...** which is able to create fuzzy sets
- 9.19.2, added new operator **... fuzzified by ...** which is able to create simple triangular fuzzy sets
- 9.19.3, added new operator **defuzzified ...** which defuzzifies a fuzzy set
- 9.19.4, added new operator **applicability [of] ...** to access a values applicability (and to set it)
- 9.20, new section **type conversion operators** which contains all type conversion operators
- 9.20.1, the **as number** operator moved from 9.16.17
- 9.20.2, the **as time** operator moved from 9.17.4
- 9.20.3, the **as string** operator moved from 9.8.13
- 9.20.4, added new operator **as truth value** which converts a number into a truth value
- 10.2.2, adjusting the **if-then-statements** to describe what happens if the condition expression evaluates to a truth value
- 10.2.3, adjusting the **switch-statements** to describe what happens if the condition expression evaluates to a truth value
- 10.2.8, added reference to the **linguistic variable definition** which is a special object type
- 11.2.18, added the **linguistic variable statement** which describes an object with only fuzzy sets as fields
- A1, changes to the **BNF** to reflect the new operators and changes to the existing statements
- A2, added reserved words: **aggregate, applicability, crisp, defuzzified, endswitch, fuzzified, fuzzy, linguistic, set, truth, value, variable**
- A4, added the new operators

X3.9   Summary of Changes from Version 2.9 to 2.10

- **A1:** Moved to A1.1 and created parent chapter to explain that either BNF or XML can be used
- **X1:** Moved non-normative appendix X1 to the normative appendix A1.2

Revision date: 4/25/2023   Print date: 10/4/2023

X3.10   Summary of Changes from Version 2.10 to 3.0

- Title: Updated version number and revision date
- 6.3.2: Section regarding FHIR support in the Data Slot
- 7.1.18: Section regarding FHIR resource mapping in Mapping Clauses, links to 11.2.1 and 11.2.2
- 8.9: Specifying that FHIR query results are constrained by standard Query rules (Primary Time, Patient relation, …) but in their execution follow HL7 FHIR read API
- 8.9.1: Primary time is retrieved from a specific field for each FHIR resource
- 8.10: FHIR resource based objects can be defined using NEW operator (not curly braces)
- 9.6.14: Special case when using Is In with FHIR Valueset in WHERE clause
- 11.2.1: Expand READ WHERE <constraint> clause to any constraint, chainable by logical operators
- 11.2.2: Special case READ AS <fhir-object-type> read statement when using FHIR object mapping
- A1 BNF: Adjusted non-terminal <data_assign_phrase> to allow the FHIR assignment statements described in Section 12

Added new sections

- 12: FHIR objects and FHIR search API can be used in Arden READ WHERE statements
- 12.1: Add introduction (FHIR version, FHIR support over curly braces, backwards compatibility and clinical landscape)
- 12.2: Support **FHIR 4.3.0**, map **patient link** and **primary time** to FHIR resource fields
- 12.2.1: Depend pre-defined Arden-FHIR objects on their FHIR documentation
- 12.3: A **patient resource** must be available in an MLM, instantiation by FHIR link
- 12.4: Primary time shall be available for each fetched FHIR object
- 12.5.1 Pre-defined objects (Valueset object)
- 12.5.2: Environment Variables (Repository, CodeSystem and Valuesets), optional default value
- 12.5.3 Valueset definition
- 12.6: Mapping of conditional READ statements (**WHERE** clause) to **FHIR search API** parameters
- 12.6.1: Schematic of Arden-FHIR read statements
- 12.6.2: Support AND, OR, NOT
- 12.6.3: Abstract search parameters available for **each FHIR resource**
- 12.6.4: Specific search parameters available for **Encounter Resource**
- 12.6.5: Specific search parameters available for **Observation Resource**
- 12.6.6: Specific search parameters available for **Condition Resource**
- 12.6.7: Specific search parameters available for **Patient Resource**
- 12.7: Full-fledged **examples** of **READ statements** mapping FHIR objects
- 12.7.1: **Environment variables** (Overwritable Resource/Service definitions)
- 12.7.2: Defining **ValueSet** from a **terminology system** and use in read statements
- 12.7.3: Example **READ** of a **FHIR Observation** object with FHIR search query
- 12.7.4: Example **READ** of a **FHIR Condition** object with FHIR search query
- 12.7.5: Example **READ** of a **FHIR Encounter** object with FHIR search query
- 12.7.6: Example **READ** of a **FHIR Patient** object with FHIR search query
- 12.7.7: Example of an **Arden AND** operator reflected in a **FHIR search query**
- 12.7.8: Example of an **Arden OR** operator reflected in a **FHIR search query**
- 12.7.9: Example of an **Arden NOT** operator reflected in a **FHIR search query**
